# Tail Recursion

A call to  $f(args)$  is usually compiled as

```
args onto stack  
invokestatic .../f
```

# Tail Recursion

A call to  $f(args)$  is usually compiled as

```
args onto stack  
invokestatic .../f
```

A call is in tail position provided:

- if Bexp then Exp else Exp
- Exp ; Exp
- Exp op Exp

then a call  $f(args)$  can be compiled as

```
prepare environment  
jump to start of function
```

# Tail Recursive Call

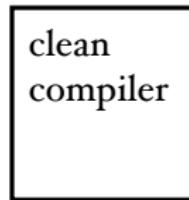

```
def compile_expT(a: Exp, env: Mem, name: String): Instrs =

**Using a compiler,  
how can you mount the  
perfect attack against a system?**

## What is a **perfect** attack?

- ➊ you can potentially completely take over a target system
- ➋ your attack is (nearly) undetectable
- ➌ the victim has (almost) no chance to recover

# Hacking Compilers

Ken Thompson  
Turing Award, 1983

Ken Thompson showed how to hide a Trojan Horse in a compiler **without** leaving any traces in the source code.

No amount of source level verification will protect you from such Thompson-hacks.

Therefore in safety-critical systems it is important to rely on only a very small TCB.

# Hacking Compilers

Ken Thompson  
Turing Award, 1983

- 1) *Assume you ship the compiler as binary and also with sources.*
- 2) *Make the compiler aware when it compiles itself.*
- 3) *Add the Trojan horse.*
- 4) *Compile.*
- 5) *Delete Trojan horse from the sources of the compiler.*
- 6) *Go on holiday for the rest of your life. ;o)*
