1 Introduction, Languages	6 While-Language
2 Regular Expressions, Derivatives	7 Compilation, JVM
3 Automata, Regular Languages	8 Compiling Functional Languages
4 Lexing, Tokenising	9 Optimisations
5 Grammars, Parsing	10 LLVM

(Basic) Regular Expressions

$r ::=$	$\mathbf{0}$	nothing
	$\mathbf{1}$	empty string / "" / []
	c	character
	$r_1 \cdot r_2$	sequence
	$r_1 + r_2$	alternative / choice
	r^*	star (zero or more)

How about ranges $[a-z]$, r^+ and $\sim r$? Do they increase the set of languages we can recognise?

Negation

Assume you have an alphabet consisting of the letters *a*, *b* and *c* only. Find a (basic!) regular expression that matches all strings *except* *ab* and *ac*!

Automata

A **deterministic finite automaton**, DFA, consists of:

- an alphabet Σ
- a set of states Q_s
- one of these states is the start state Q_0
- some states are accepting states F , and
- there is transition function δ

which takes a state as argument and a character and produces a new state; this function might not be everywhere defined \Rightarrow partial function

$$A(\Sigma, Q_s, Q_0, F, \delta)$$

- the start state can be an accepting state
- it is possible that there is no accepting state
- all states might be accepting (but this does not necessarily mean all strings are accepted)

for this automaton δ is the function

$$\begin{array}{lll}
 (Q_0, a) \rightarrow Q_1 & (Q_1, a) \rightarrow Q_4 & (Q_4, a) \rightarrow Q_4 \\
 (Q_0, b) \rightarrow Q_2 & (Q_1, b) \rightarrow Q_2 & (Q_4, b) \rightarrow Q_4 \dots
 \end{array}$$

Accepting a String

Given

$$A(\Sigma, Q_s, Q_0, F, \delta)$$

you can define

$$\begin{aligned}\hat{\delta}(Q, []) &\stackrel{\text{def}}{=} Q \\ \hat{\delta}(Q, c :: s) &\stackrel{\text{def}}{=} \hat{\delta}(\delta(Q, c), s)\end{aligned}$$

Accepting a String

Given

$$A(\Sigma, Q_s, Q_0, F, \delta)$$

you can define

$$\begin{aligned}\hat{\delta}(Q, []) &\stackrel{\text{def}}{=} Q \\ \hat{\delta}(Q, c :: s) &\stackrel{\text{def}}{=} \hat{\delta}(\delta(Q, c), s)\end{aligned}$$

Whether a string s is accepted by A ?

$$\hat{\delta}(Q_0, s) \in F$$

Regular Languages

A **language** is a set of strings.

A **regular expression** specifies a language.

A language is **regular** iff there exists a regular expression that recognises all its strings.

Regular Languages

A **language** is a set of strings.

A **regular expression** specifies a language.

A language is **regular** iff there exists a regular expression that recognises all its strings.

not all languages are regular, e.g. $a^n b^n$ is not

Regular Languages (2)

A language is **regular** iff there exists a regular expression that recognises all its strings.

or **equivalently**

A language is **regular** iff there exists a deterministic finite automaton that recognises all its strings.

Non-Deterministic Finite Automata

$$N(\Sigma, Q_s, Q_{s_0}, F, \rho)$$

A non-deterministic finite automaton (NFA) consists of:

- a finite set of states, Q_s
- some these states are the start states, Q_{s_0}
- some states are accepting states, and
- there is transition **relation**, ρ

$$\begin{aligned}(Q_1, a) &\rightarrow Q_2 \\ (Q_1, a) &\rightarrow Q_3 \quad \dots\end{aligned}$$

Non-Deterministic Finite Automata

$N(\Sigma, Q_s, Q_{s_0}, F, \rho)$

A non-deterministic finite automaton (NFA) consists of:

- a finite set of states, Q_s
- some these states are the start states, Q_{s_0}
- some states are accepting states, and
- there is transition **relation**, ρ

$$\begin{array}{l} (Q_1, a) \rightarrow Q_2 \\ (Q_1, a) \rightarrow Q_3 \end{array} \dots (Q_1, a) \rightarrow \{Q_2, Q_3\}$$

An NFA Example

Another Example

For the regular expression $(.*)a(.^{\{n\}})bc$

Note the star-transitions: accept any character.

Two Epsilon NFA Examples

Thompson: Rexp to ϵ NFA

0 start \rightarrow 

1 start \rightarrow 

c start \rightarrow 

Case $r_1 \cdot r_2$

By recursion we are given two automata:

We need to (1) change the accepting nodes of the first automaton into non-accepting nodes, and (2) connect them via ϵ -transitions to the starting state of the second automaton.

Case $r_1 \cdot r_2$

By recursion we are given two automata:

We need to (1) change the accepting nodes of the first automaton into non-accepting nodes, and (2) connect them via ϵ -transitions to the starting state of the second automaton.

Case $r_1 + r_2$

By recursion we are given two automata:

We can just put both automata together.

Case $r_1 + r_2$

By recursion we are given two automata:

We can just put both automata together.

Case r^*

By recursion we are given an automaton for r :

Case r^*

By recursion we are given an automaton for r :

Case r^*

By recursion we are given an automaton for r :

Why can't we just have an epsilon transition from the accepting states to the starting state?

NFA Breadth-First: $a^?{n} \cdot a{n}$

NFA Breadth-First: $(a^*)^* \cdot b$

NFA Depth-First: $a^{\{n\}} \cdot a^{\{n\}}$

NFA Depth-First: $(a^*)^* \cdot b$

The punchline is that many existing libraries do depth-first search in NFAs (with backtracking).

Regexps and Automata

Thompson's construction subset construction

Regexps  NFAs  DFAs

Regexps and Automata

DFA Minimisation

1. Take all pairs (q, p) with $q \neq p$
2. Mark all pairs that accepting and non-accepting states
3. For all unmarked pairs (q, p) and all characters c test whether

$$(\delta(q, c), \delta(p, c))$$

are marked. If yes in at least one case, then also mark (q, p) .

4. Repeat last step until no change.
5. All unmarked pairs can be merged.

Regexps and Automata

Regexps and Automata

DFA to Rexp

You know how to solve since school days, no?

$$Q_0 = 2Q_0 + 3Q_1 + 4Q_2$$

$$Q_1 = 2Q_0 + 3Q_1 + 1Q_2$$

$$Q_2 = 1Q_0 + 5Q_1 + 2Q_2$$

$$Q_0 = Q_0 b + Q_1 b + Q_2 b + \mathbf{1}$$

$$Q_1 = Q_0 a$$

$$Q_2 = Q_1 a + Q_2 a$$

substitute Q_1 into Q_0 & Q_2 :

$$Q_0 = Q_0 b + Q_0 a b + Q_2 b + 1$$

$$Q_2 = Q_0 a a + Q_2 a$$

$$Q_0 = Q_0 b + Q_1 b + Q_2 b + 1$$

$$Q_1 = Q_0 a$$

$$Q_2 = Q_1 a + Q_2 a$$

substitute Q_1 into Q_0 & Q_2 :

$$Q_0 = Q_0 b + Q_0 a b + Q_2 b + 1$$

$$Q_2 = Q_0 a a + Q_2 a$$

simplifying Q_0 :

$$Q_0 = Q_0 (b + a b) + Q_2 b + 1$$

$$Q_2 = Q_0 a a + Q_2 a$$

$$Q_0 = Q_0 b + Q_1 b + Q_2 b + 1$$

$$Q_1 = Q_0 a$$

$$Q_2 = Q_1 a + Q_2 a$$

substitute Q_1 into Q_0 & Q_2 :

$$Q_0 = Q_0 b + Q_0 a b + Q_2 b + 1$$

$$Q_2 = Q_0 a a + Q_2 a$$

simplifying Q_0 :

$$Q_0 = Q_0 (b + a b) + Q_2 b + 1$$

$$Q_2 = Q_0 a a + Q_2 a$$

$$Q_0 = Q_0 b + Q_1 b + Q_2 b + 1$$

$$Q_1 = Q_0 a$$

Arden's Lemma:

$$\text{If } q = qr + s \text{ then } q = sr^*$$

substitute Q_1 into Q_0 & Q_2 :

$$Q_0 = Q_0 b + Q_0 a b + Q_2 b + 1$$

$$Q_2 = Q_0 a a + Q_2 a$$

simplifying Q_0 :

$$Q_0 = Q_0 (b + a b) + Q_2 b + 1$$

$$Q_2 = Q_0 a a + Q_2 a$$

Arden for Q_2 :

$$Q_0 = Q_0 (b + a b) + Q_2 b + 1$$

$$Q_2 = Q_0 a a (a^*)$$

$$Q_1 = Q_0 a$$

Arden's Lemma:

$$\text{If } q = q r + s \text{ then } q = s r^*$$

substitute Q_1 into Q_0 & Q_2 :

$$Q_0 = Q_0 b + Q_0 a b + Q_2 b + 1$$

$$Q_2 = Q_0 a a + Q_2 a$$

simplifying Q_0 :

$$Q_0 = Q_0 (b + a b) + Q_2 b + 1$$

$$Q_2 = Q_0 a a + Q_2 a$$

Arden for Q_2 :

$$Q_0 = Q_0 (b + a b) + Q_2 b + 1$$

$$Q_2 = Q_0 a a (a^*)$$

$Q_1 =$
 $Q_2 =$

Substitute Q_2 and simplify:

$$Q_0 = Q_0 (b + a b + a a (a^*) b) + 1$$

substitute Q_1 into Q_0 & Q_2 :

$$Q_0 = Q_0 b + Q_0 a b + Q_2 b + 1$$

$$Q_2 = Q_0 a a + Q_2 a$$

simplifying Q_0 :

$$Q_0 = Q_0 (b + a b) + Q_2 b + 1$$

$$Q_2 = Q_0 a a + Q_2 a$$

Arden's Lemma:

$$\text{If } q = q r + s \text{ then } q = s r^*$$

1

$$\begin{aligned} Q_1 &= \\ Q_2 &= \end{aligned}$$

Substitute Q_2 and simplify:

$$Q_0 = Q_0 (b + a b + a a (a^*) b) + 1$$

Arden again for Q_0 :

$$Q_0 = (b + a b + a a (a^*) b)^*$$

substitute Q_1 into Q_0 & Q_2 :

$$Q_0 = Q_0 b + Q_0 a b + Q_2 b + 1$$

$$Q_2 = Q_0 a a + Q_2 a$$

simplifying Q_0 :

$$Q_0 = Q_0 (b + a b) + Q_2 b + 1$$

$$Q_2 = Q_0 a a + Q_2 a$$

Arden for Q_2 :

$$Q_0 = Q_0 (b + a b) + Q_2 b + 1$$

$$Q_2 = Q_0 a a (a^*)$$

$Q_1 =$
 $Q_2 =$

Substitute Q_2 into Q_0 & Q_1 :

$$Q_0 = Q_0$$

Finally:

$$Q_0 = (b + a b + a a (a^*) b)^*$$

$$Q_1 = (b + a b + a a (a^*) b)^* a$$

$$Q_2 = (b + a b + a a (a^*) b)^* a a (a^*)$$

Arden
 Q_0

$$Q_0 = Q_0 b + Q_1 b + Q_2 b + 1$$

$$Q_1 = Q_0 a$$

$$Q_2 = Q_1 a + Q_2 a$$

Finally:

$$Q_0 = (b + ab + aa(a^*)b)^*$$

$$Q_1 = (b + ab + aa(a^*)b)^* a$$

$$Q_2 = (b + ab + aa(a^*)b)^* aa(a^*)$$

Regexps and Automata

Regular Languages (3)

A language is **regular** iff there exists a regular expression that recognises all its strings.

or **equivalently**

A language is **regular** iff there exists a deterministic finite automaton that recognises all its strings.

Regular Languages (3)

A language is **regular** iff there exists a regular expression that recognises all its strings.

or **equivalently**

A language is **regular** iff there exists a deterministic finite automaton that recognises all its strings.

Why is every finite set of strings a regular language?

Regexps and Automata

Regular Languages

Two equivalent definitions:

A language is **regular** iff there exists a regular expression that recognises all its strings.

A language is **regular** iff there exists an automaton that recognises all its strings.

for example $a^n b^n$ is not regular

Negation

Regular languages are closed under negation:

But requires that the automaton is **completed**!

Negation

Regular languages are closed under negation:

But requires that the automaton is **completed!**

$$(a^*)^* \cdot b$$

Which language?

I always thought dfa's needed a transition for each state for each character, and if not it would be an nfa not a dfa. Is there an example that disproves this?

Do the regular expression matchers in Python and Java 8 have more features than the one implemented in this module? Or is there another reason for their inefficiency?

- CW / censored some msgs
- power law / proof
- CW feedback
- too polished CW submissions
