The Goal of this Course

Write a compiler

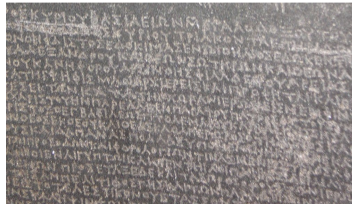

Today a lexer.

lexing \Rightarrow recognising words (Stone of Rosetta)

Regular Expressions

In programming languages they are often used to recognise:

- operands, digits
- identifiers
- numbers (non-leading zeros)
- keywords
- comments

Lexing: Test Case

```
write "Fib";  
read n;  
minus1 := 0;  
minus2 := 1;  
while n > 0 do {  
    temp := minus2;  
    minus2 := minus1 + minus2;  
    minus1 := temp;  
    n := n - 1  
};  
write "Result";  
write minus2
```

There is one small problem with the tokenizer. How should we tokenize...?

"x-3"

ID: ...

OP:

"+", "-"

NUM:

(NONZERODIGIT · DIGIT*) + '0'

NUMBER:

NUM + ("-" · NUM)

The same problem with

$$(ab + a) \cdot (c + bc)$$

and the string *abc*.

The same problem with

$$(ab + a) \cdot (c + bc)$$

and the string *abc*.

Or, keywords are **if** etc and identifiers are letters followed by “letters + numbers + _”*

`if` `iffoo`

Simplification

- If we simplify after the derivative, then we are building the value for the simplified regular expression, but **not** for the original regular expression.

Simplification

- If we simplify after the derivative, then we are building the value for the simplified regular expression, but **not** for the original regular expression.

$$(0 \cdot (b \cdot c)) + ((0 \cdot c) + 1) \mapsto 1$$

Normally we would have

$$(0 \cdot (b \cdot c)) + ((0 \cdot c) + 1)$$

and answer how this regular expression matches the empty string with the value

$$\textit{Right}(\textit{Right}(\textit{Empty}))$$

But now we simplify this to **1** and would produce *Empty* (see *mkeys*).
