Abstract. Brzozowski introduced the notion of derivatives for regular expressions. They can be used for a very simple regular expression matching algorithm. Sulzmann and Lu cleverly extended this algorithm in order to deal with POSIX matching, which is the underlying disambiguation strategy for regular expressions needed in lexers. Their algorithm generates POSIX values which encode the information of how a regular expression matches a string—that is, which part of the string is matched by which part of the regular expression. In this paper we give our inductive definition of what a POSIX value is and show (i) that such a value is unique (for given regular expression and string being matched) and (ii) that Sulzmann and Lu's algorithm always generates such a value (provided that the regular expression matches the string). We show that (iii) our inductive definition of a POSIX value is equivalent to an alternative definition by Okui and Suzuki which identifies POSIX values as least elements according to an ordering of values. We also prove the correctness of Sulzmann's bitcoded version of the POSIX matching algorithm and extend the results to additional constructors for regular expressions.

Keywords: POSIX matching, Derivatives of Regular Expressions, Isabelle/HOL

1 Core of the proof

This paper builds on previous work by Ausaf and Urban using regular expression'd bit-coded derivatives to do lexing that is both fast and satisfies the POSIX

^{*} This paper is a revised and expanded version of [2]. Compared with that paper we give a second definition for POSIX values introduced by Okui Suzuki [10,11] and prove that it is equivalent to our original one. This second definition is based on an ordering of values and very similar to, but not equivalent with, the definition given by Sulzmann and Lu [13]. The advantage of the definition based on the ordering is that it implements more directly the informal rules from the POSIX standard. We also prove Sulzmann & Lu's conjecture that their bitcoded version of the POSIX algorithm is correct. Furthermore we extend our results to additional constructors of regular expressions.

specification. In their work, a bit-coded algorithm introduced by Sulzmann and Lu was formally verified in Isabelle, by a very clever use of flex function and retrieve to carefully mimic the way a value is built up by the injection function.

In the previous work, Ausaf and Urban established the below equality:

Lemma 1. If
$$v: r \setminus s$$
 then Some (flex $r id s v$) = decode (retrieve $(r^{\uparrow} \setminus s) v$) r .

This lemma establishes a link with the lexer without bit-codes. With it we get the correctness of bit-coded algorithm.

```
Lemma 2. lexer_h r s = lexer r s
```

However what is not certain is whether we can add simplification to the bit-coded algorithm, without breaking the correct lexing output.

The reason that we do need to add a simplification phase after each derivative step of *blexer* is because it produces intermediate regular expressions that can grow exponentially. For example, the regular expression $(a + aa)^*$ after taking derivative against just 10 as will have size 8192.

Therefore, we insert a simplification phase after each derivation step, as defined below:

Lemma 3. blexer__simp
$$r s \stackrel{def}{=} if nullable_b (bders__simp (r^{\uparrow}) s)$$
 then decode $(mkeps_b (bders__simp (r^{\uparrow}) s))$ r else None

The simplification function is given as follows:

```
bsimp \; (ASEQ \; bs \; r_1 \; r_2) \; \stackrel{\text{def}}{=} \; bsimp\_\_ASEQ \; bs \; (bsimp \; r_1) \; (bsimp \; r_2)
bsimp \; (AALTs \; bs1.0 \; rs) \; \stackrel{\text{def}}{=} \; bsimp\_\_AALTs \; bs1.0 \; (distinctBy \; (flts \; (map \; bsimp \; rs)) \; erase \; \varnothing)
bsimp \; AZERO \; \stackrel{\text{def}}{=} \; AZERO
```

And the two helper functions are:

This might sound trivial in the case of producing a YES/NO answer, but once we require a lexing output to be produced (which is required in applications like compiler front-end, malicious attack domain extraction, etc.), it is not straightforward if we still extract what is needed according to the POSIX standard

By simplification, we mean specifically the following rules:

$$\overline{ASEQ}$$
 bs \overline{AZERO} $r_2 \rightsquigarrow \overline{AZERO}$

$$\overline{ASEQ \ bs \ r_1 \ AZERO} \leadsto AZERO$$

$$\overline{ASEQ~bs~(AONE~bs_1)~r_1 \leadsto fuse~(bs~@~bs_1)~r_1} \\ \underline{r_1 \leadsto r_2} \\ \overline{ASEQ~bs~r_1~r_3 \leadsto ASEQ~bs~r_2~r_3} \\ \underline{r_3 \leadsto r_4} \\ \overline{ASEQ~bs~r_1~r_3 \leadsto ASEQ~bs~r_1~r_4} \\ \underline{r \leadsto r'} \\ \overline{AALTs~bs~(rs_1~@~[r]~@~rs_2) \leadsto AALTs~bs~(rs_1~@~[r']~@~rs_2)}$$

$$\overline{AALTs \ bs \ (rs_a @ [AZERO] @ rs_b)} \leadsto AALTs \ bs \ (rs_a @ rs_b)$$

$$\overline{AALTs\ bs\ (rs_a\ @\ [AALTs\ bs_1\ rs_1]\ @\ rs_b)} \leadsto AALTs\ bs\ (rs_a\ @\ map\ (fuse\ bs_1)\ rs_1\ @\ rs_b)$$

And these can be made compact by the following simplification function: where the function $bsimp_AALTs$

The core idea of the proof is that two regular expressions, if "isomorphic" up to a finite number of rewrite steps, will remain "isomorphic" when we take the same sequence of derivatives on both of them. This can be expressed by the following rewrite relation lemma:

Lemma 4.
$$(r \backslash s) \leadsto bders_simp \ r \ s$$

This isomorphic relation implies a property that leads to the correctness result: if two (nullable) regular expressions are "rewritable" in many steps from one another, then a call to function bmkeps gives the same bit-sequence:

Lemma 5. If $r1.0 \rightsquigarrow r2.0$ and $nullable_b r1.0$ then $mkeps_b r1.0 = mkeps_b r2.0$

Given the same bit-sequence, the decode function will give out the same value, which is the output of both lexers:

Lemma 6. lexer_b $r s \stackrel{def}{=} if nullable_b (r^{\uparrow} \backslash \! s) then decode (mkeps_b (r^{\uparrow} \backslash \! s)) <math>r$ else None

Lemma 7. blexer__simp r s $\stackrel{def}{=}$ if nullable_b (bders__simp (r^{\uparrow}) s) then decode (mkeps_b (bders__simp (r^{\uparrow}) s)) r else None

And that yields the correctness result:

Lemma 8. $lexer r s = blexer_simp r s$

The nice thing about the above

2 Additional Simp Rules?

One question someone would ask is: can we add more "atomic" simplification/rewriting rules, so the simplification is even more aggressive, making the intermediate results smaller, and therefore more space-efficient? For example, one might want to do open up alternatives who is a child of a sequence:

ASEQ bs (AALTs bs1 rs)
$$r \rightsquigarrow ?$$
 AALTs (bs @ bs1) (map ($\lambda r'$. ASEQ [] r' r) rs)

This rule allows us to simplify $(a + b) \cdot c + a \cdot c$ into $a \cdot c + b \cdot c$, which cannot be done under the rrewrite rule because only alternatives which are children of another alternative can be spilled out.

Now with this rule we have some examples where we get even smaller intermediate derivatives than not having this rule: $(a+aa)^* \to (1+1a)(a+aa)^* \to (1+a)(a+aa)^*$

3 Introduction

Brzozowski [3] introduced the notion of the derivative $r \setminus c$ of a regular expression r w.r.t. a character c, and showed that it gave a simple solution to the problem of matching a string s with a regular expression r: if the derivative of r w.r.t. (in succession) all the characters of the string matches the empty string, then r matches s (and vice versa). The derivative has the property (which may almost be regarded as its specification) that, for every string s and regular expression r and character c, one has $cs \in L(r)$ if and only if $s \in L(r \setminus c)$. The beauty of Brzozowski's derivatives is that they are neatly expressible in any functional language, and easily definable and reasoned about in theorem provers—the definitions just consist of inductive datatypes and simple recursive functions. A mechanised correctness proof of Brzozowski's matcher in for example HOL4 has been mentioned by Owens and Slind [12]. Another one in Isabelle/HOL is part of the work by Krauss and Nipkow [8]. And another one in Coq is given by Coquand and Siles [4].

If a regular expression matches a string, then in general there is more than one way of how the string is matched. There are two commonly used disambiguation strategies to generate a unique answer: one is called GREEDY matching [5] and the other is POSIX matching [1,9,10,13,14]. For example consider the string xy and the regular expression $(x + y + xy)^*$. Either the string can be matched in two 'iterations' by the single letter-regular expressions x and y, or directly in one iteration by xy. The first case corresponds to GREEDY matching, which first matches with the left-most symbol and only matches the next symbol in case of a mismatch (this is greedy in the sense of preferring instant gratification to delayed repletion). The second case is POSIX matching, which prefers the longest match.

In the context of lexing, where an input string needs to be split up into a sequence of tokens, POSIX is the more natural disambiguation strategy for what

programmers consider basic syntactic building blocks in their programs. These building blocks are often specified by some regular expressions, say r_{key} and r_{id} for recognising keywords and identifiers, respectively. There are a few underlying (informal) rules behind tokenising a string in a POSIX [1] fashion:

- The Longest Match Rule (or "Maximal Munch Rule"): The longest initial substring matched by any regular expression is taken as next token.
- Priority Rule: For a particular longest initial substring, the first (leftmost) regular expression that can match determines the token.
- Star Rule: A subexpression repeated by * shall not match an empty string unless this is the only match for the repetition.
- Empty String Rule: An empty string shall be considered to be longer than no match at all.

Consider for example a regular expression r_{key} for recognising keywords such as if, then and so on; and r_{id} recognising identifiers (say, a single character followed by characters or numbers). Then we can form the regular expression $(r_{key} + r_{id})^*$ and use POSIX matching to tokenise strings, say iffoo and if. For iffoo we obtain by the Longest Match Rule a single identifier token, not a keyword followed by an identifier. For if we obtain by the Priority Rule a keyword token, not an identifier token—even if r_{id} matches also. By the Star Rule we know $(r_{key} + r_{id})^*$ matches iffoo, respectively if, in exactly one 'iteration' of the star. The Empty String Rule is for cases where, for example, the regular expression $(a^*)^*$ matches against the string bc. Then the longest initial matched substring is the empty string, which is matched by both the whole regular expression and the parenthesised subexpression.

One limitation of Brzozowski's matcher is that it only generates a YES/NO answer for whether a string is being matched by a regular expression. Sulzmann and Lu [13] extended this matcher to allow generation not just of a YES/NO answer but of an actual matching, called a [lexical] value. Assuming a regular expression matches a string, values encode the information of how the string is matched by the regular expression—that is, which part of the string is matched by which part of the regular expression. For this consider again the string xy and the regular expression $(x + (y + xy))^*$ (this time fully parenthesised). We can view this regular expression as tree and if the string xy is matched by two Star 'iterations', then the x is matched by the left-most alternative in this tree and the y by the right-left alternative. This suggests to record this matching as

Stars [Left (Char
$$x$$
), Right (Left (Char y))]

where Stars, Left, Right and Char are constructors for values. Stars records how many iterations were used; Left, respectively Right, which alternative is used. This 'tree view' leads naturally to the idea that regular expressions act as types and values as inhabiting those types (see, for example, [7]). The value for matching xy in a single 'iteration', i.e. the POSIX value, would look as follows

where Stars has only a single-element list for the single iteration and Seq indicates that xy is matched by a sequence regular expression.

Sulzmann and Lu give a simple algorithm to calculate a value that appears to be the value associated with POSIX matching. The challenge then is to specify that value, in an algorithm-independent fashion, and to show that Sulzmann and Lu's derivative-based algorithm does indeed calculate a value that is correct according to the specification. The answer given by Sulzmann and Lu [13] is to define a relation (called an "order relation") on the set of values of r, and to show that (once a string to be matched is chosen) there is a maximum element and that it is computed by their derivative-based algorithm. This proof idea is inspired by work of Frisch and Cardelli [5] on a GREEDY regular expression matching algorithm. However, we were not able to establish transitivity and totality for the "order relation" by Sulzmann and Lu. There are some inherent problems with their approach (of which some of the proofs are not published in [13]); perhaps more importantly, we give in this paper a simple inductive (and algorithm-independent) definition of what we call being a POSIX value for a regular expression r and a string s; we show that the algorithm by Sulzmann and Lu computes such a value and that such a value is unique. Our proofs are both done by hand and checked in Isabelle/HOL. The experience of doing our proofs has been that this mechanical checking was absolutely essential: this subject area has hidden snares. This was also noted by Kuklewicz [9] who found that nearly all POSIX matching implementations are "buggy" [13, Page 203] and by Grathwohl et al [6, Page 36] who wrote:

"The POSIX strategy is more complicated than the greedy because of the dependence on information about the length of matched strings in the various subexpressions."

Contributions: We have implemented in Isabelle/HOL the derivative-based regular expression matching algorithm of Sulzmann and Lu [13]. We have proved the correctness of this algorithm according to our specification of what a POSIX value is (inspired by work of Vansummeren [14]). Sulzmann and Lu sketch in [13] an informal correctness proof: but to us it contains unfillable gaps. Our specification of a POSIX value consists of a simple inductive definition that given a string and a regular expression uniquely determines this value. We also show that our definition is equivalent to an ordering of values based on positions by Okui and Suzuki [10].

We extend our results to ??? Bitcoded version??

⁴ An extended version of [13] is available at the website of its first author; this extended version already includes remarks in the appendix that their informal proof contains gaps, and possible fixes are not fully worked out.

4 Preliminaries

Strings in Isabelle/HOL are lists of characters with the empty string being represented by the empty list, written [], and list-cons being written as $_::_$. Often we use the usual bracket notation for lists also for strings; for example a string consisting of just a single character c is written [c]. We use the usual definitions for prefixes and strict prefixes of strings. By using the type char for characters we have a supply of finitely many characters roughly corresponding to the ASCII character set. Regular expressions are defined as usual as the elements of the following inductive datatype:

$$r := \mathbf{0} \mid \mathbf{1} \mid c \mid r_1 + r_2 \mid r_1 \cdot r_2 \mid r^*$$

where $\mathbf{0}$ stands for the regular expression that does not match any string, $\mathbf{1}$ for the regular expression that matches only the empty string and c for matching a character literal. The language of a regular expression is also defined as usual by the recursive function L with the six clauses:

(1)
$$L(\mathbf{0}) \stackrel{\text{def}}{=} \varnothing$$

(2) $L(\mathbf{1}) \stackrel{\text{def}}{=} \{[]\}$
(3) $L(c) \stackrel{\text{def}}{=} \{[c]\}$
(4) $L(r_1 \cdot r_2) \stackrel{\text{def}}{=} L(r_1) @ L(r_2)$
(5) $L(r_1 + r_2) \stackrel{\text{def}}{=} L(r_1) \cup L(r_2)$
(6) $L(r^*) \stackrel{\text{def}}{=} (L(r)) \star$

In clause (4) we use the operation _ @ _ for the concatenation of two languages (it is also list-append for strings). We use the star-notation for regular expressions and for languages (in the last clause above). The star for languages is defined inductively by two clauses: (i) the empty string being in the star of a language and (ii) if s_1 is in a language and s_2 in the star of this language, then also s_1 @ s_2 is in the star of this language. It will also be convenient to use the following notion of a semantic derivative (or left quotient) of a language defined as

$$Der \ c \ A \stackrel{def}{=} \{s \mid c :: s \in A\} \ .$$

For semantic derivatives we have the following equations (for example mechanically proved in [8]):

$$\begin{array}{lll} Der\ c\ \varnothing &\stackrel{\mathrm{def}}{=}\ \varnothing \\ Der\ c\ \{[]\} &\stackrel{\mathrm{def}}{=}\ \varnothing \\ Der\ c\ \{[d]\} &\stackrel{\mathrm{def}}{=}\ if\ c=d\ then\ \{[]\}\ else\ \varnothing \\ Der\ c\ (A\cup B) &\stackrel{\mathrm{def}}{=}\ Der\ c\ A\cup Der\ c\ B \\ Der\ c\ (A\ @\ B) &\stackrel{\mathrm{def}}{=}\ (Der\ c\ A\ @\ B)\cup (if\ []\ \in\ A\ then\ Der\ c\ B\ else\ \varnothing) \\ Der\ c\ (A\star) &\stackrel{\mathrm{def}}{=}\ Der\ c\ A\ @\ A\star \end{array}$$

Brzozowski's derivatives of regular expressions [3] can be easily defined by two recursive functions: the first is from regular expressions to booleans (implementing a test when a regular expression can match the empty string), and the second takes a regular expression and a character to a (derivative) regular expression:

```
\stackrel{\mathrm{def}}{=} \mathit{False}
 nullable (0)
                                                       \stackrel{\mathrm{def}}{=} \mathit{True}
 nullable (1)
                                                        \stackrel{\mathrm{def}}{=} \mathit{False}
 nullable\ (c) \ \stackrel{\mathrm{def}}{=} \mathit{False} nullable\ (r_1 + r_2) \stackrel{\mathrm{def}}{=} \mathit{nullable}\ r_1 \lor \mathit{nullable}\ r_2
                                                        \stackrel{\text{def}}{=} nullable r_1 \wedge nullable r_2
 nullable (r_1 \cdot r_2)
                                                         \stackrel{\mathrm{def}}{=} \mathit{True}
 nullable (r^*)
                                                         \stackrel{\text{def}}{=} 0
 \mathbf{0} \backslash c
                                                         \stackrel{\text{def}}{=} \mathbf{0}
 \mathbf{1} \backslash c
d \ c \\ (r_1 + r_2) \ c \\ (r_1 \cdot r_2) \ c
                                                        \stackrel{\text{def}}{=} if c = d then 1 else 0
                                                      \stackrel{\text{def}}{=} (r_1 \backslash c) + (r_2 \backslash c)
\stackrel{\text{def}}{=} if \ nullable \ r_1 \ then \ (r_1 \backslash c) \cdot r_2 + (r_2 \backslash c) \ else \ (r_1 \backslash c) \cdot r_2
 (r^{\star}) \backslash c
```

We may extend this definition to give derivatives w.r.t. strings:

$$r \setminus [] \stackrel{\text{def}}{=} r$$

 $r \setminus (c :: s) \stackrel{\text{def}}{=} (r \setminus c) \setminus s$

Given the equations in (1), it is a relatively easy exercise in mechanical reasoning to establish that

Proposition 1.

(1) nullable
$$r$$
 if and only if $[] \in L(r)$, and (2) $L(r \setminus c) = Der c (L(r))$.

With this in place it is also very routine to prove that the regular expression matcher defined as

$$match \ r \ s \stackrel{def}{=} nullable \ (r \backslash s)$$

gives a positive answer if and only if $s \in L(r)$. Consequently, this regular expression matching algorithm satisfies the usual specification for regular expression matching. While the matcher above calculates a provably correct YES/NO answer for whether a regular expression matches a string or not, the novel idea of Sulzmann and Lu [13] is to append another phase to this algorithm in order to calculate a [lexical] value. We will explain the details next.

5 POSIX Regular Expression Matching

There have been many previous works that use values for encoding *how* a regular expression matches a string. The clever idea by Sulzmann and Lu [13] is to define a function on values that mirrors (but inverts) the construction of the derivative on regular expressions. *Values* are defined as the inductive datatype

$$v := \mathit{Empty} \mid \mathit{Char} \ c \mid \mathit{Left} \ v \mid \mathit{Right} \ v \mid \mathit{Seq} \ v_1 \ v_2 \mid \mathit{Stars} \ vs$$

where we use vs to stand for a list of values. (This is similar to the approach taken by Frisch and Cardelli for GREEDY matching [5], and Sulzmann and Lu for POSIX matching [13]). The string underlying a value can be calculated by the *flat* function, written $|_|$ and defined as:

$$|Empty| \stackrel{\text{def}}{=} [] \qquad |Seq \ v_1 \ v_2| \stackrel{\text{def}}{=} |v_1| \ @ \ |v_2|$$

$$|Char \ c| \stackrel{\text{def}}{=} [c] \qquad |Stars \ []| \stackrel{\text{def}}{=} []$$

$$|Left \ v| \stackrel{\text{def}}{=} |v| \qquad |Stars \ (v :: vs)| \stackrel{\text{def}}{=} |v| \ @ \ |Stars \ vs|$$

$$|Right \ v| \stackrel{\text{def}}{=} |v|$$

We will sometimes refer to the underlying string of a value as *flattened value*. We will also overload our notation and use |vs| for flattening a list of values and concatenating the resulting strings.

Sulzmann and Lu define inductively an inhabitation relation that associates values to regular expressions. We define this relation as follows: 5

where in the clause for Stars we use the notation $v \in vs$ for indicating that v is a member in the list vs. We require in this rule that every value in vs flattens to a non-empty string. The idea is that Stars-values satisfy the informal Star Rule (see Introduction) where the \star does not match the empty string unless this is the only match for the repetition. Note also that no values are associated with the regular expression $\mathbf{0}$, and that the only value associated with the regular expression $\mathbf{1}$ is Empty. It is routine to establish how values "inhabiting" a regular expression correspond to the language of a regular expression, namely

⁵ Note that the rule for *Stars* differs from our earlier paper [2]. There we used the original definition by Sulzmann and Lu which does not require that the values $v \in vs$ flatten to a non-empty string. The reason for introducing the more restricted version of lexical values is convenience later on when reasoning about an ordering relation for values.

Proposition 2.
$$L(r) = \{|v| | v : r\}$$

Given a regular expression r and a string s, we define the set of all *Lexical Values* inhabited by r with the underlying string being s:⁶

$$LV \ r \ s \stackrel{def}{=} \{ v \mid v : r \land |v| = s \}$$

The main property of LV r s is that it is alway finite.

Proposition 3. finite (LV r s)

This finiteness property does not hold in general if we remove the side-condition about $|v| \neq []$ in the *Stars*-rule above. For example using Sulzmann and Lu's less restrictive definition, LV ($\mathbf{1}^{\star}$) [] would contain infinitely many values, but according to our more restricted definition only a single value, namely LV ($\mathbf{1}^{\star}$) $[] = \{Stars []\}.$

If a regular expression r matches a string s, then generally the set LV r s is not just a singleton set. In case of POSIX matching the problem is to calculate the unique lexical value that satisfies the (informal) POSIX rules from the Introduction. Graphically the POSIX value calculation algorithm by Sulzmann and Lu can be illustrated by the picture in Figure 1 where the path from the left to the right involving derivatives/nullable is the first phase of the algorithm (calculating successive Brzozowski's derivatives) and mkeps/inj, the path from right to left, the second phase. This picture shows the steps required when a regular expression, say r_1 , matches the string [a, b, c]. We first build the three derivatives (according to a, b and c). We then use nullable to find out whether the resulting derivative regular expression r_4 can match the empty string. If yes, we call the function mkeps that produces a value v_4 for how r_4 can match the empty string (taking into account the POSIX constraints in case there are several ways). This function is defined by the clauses:

Note that this function needs only to be partially defined, namely only for regular expressions that are nullable. In case nullable fails, the string [a, b, c] cannot be matched by r_1 and the null value None is returned. Note also how this function makes some subtle choices leading to a POSIX value: for example if an alternative regular expression, say $r_1 + r_2$, can match the empty string and furthermore r_1 can match the empty string, then we return a Left-value. The Right-value will only be returned if r_1 cannot match the empty string.

⁶ Okui and Suzuki refer to our lexical values as *canonical values* in [10]. The notion of *non-problematic values* by Cardelli and Frisch [5] is related, but not identical to our lexical values.

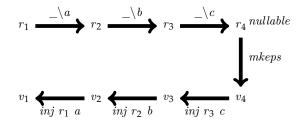

Fig. 1. The two phases of the algorithm by Sulzmann & Lu [13], matching the string [a, b, c]. The first phase (the arrows from left to right) is Brzozowski's matcher building successive derivatives. If the last regular expression is *nullable*, then the functions of the second phase are called (the top-down and right-to-left arrows): first *mkeps* calculates a value v_4 witnessing how the empty string has been recognised by r_4 . After that the function inj "injects back" the characters of the string into the values.

The most interesting idea from Sulzmann and Lu [13] is the construction of a value for how r_1 can match the string [a, b, c] from the value how the last derivative, r_4 in Fig. 1, can match the empty string. Sulzmann and Lu achieve this by stepwise "injecting back" the characters into the values thus inverting the operation of building derivatives, but on the level of values. The corresponding function, called inj, takes three arguments, a regular expression, a character and a value. For example in the first (or right-most) inj-step in Fig. 1 the regular expression r_3 , the character c from the last derivative step and v_4 , which is the value corresponding to the derivative regular expression r_4 . The result is the new value v_3 . The final result of the algorithm is the value v_1 . The inj function is defined by recursion on regular expressions and by analysing the shape of values (corresponding to the derivative regular expressions).

```
 \begin{array}{lll} (1) & inj \ d \ c \ (Empty) & \stackrel{\text{def}}{=} \ Char \ d \\ (2) & inj \ (r_1 + r_2) \ c \ (Left \ v_1) & \stackrel{\text{def}}{=} \ Left \ (inj \ r_1 \ c \ v_1) \\ (3) & inj \ (r_1 + r_2) \ c \ (Right \ v_2) & \stackrel{\text{def}}{=} \ Right \ (inj \ r_2 \ c \ v_2) \\ (4) & inj \ (r_1 \cdot r_2) \ c \ (Seq \ v_1 \ v_2) & \stackrel{\text{def}}{=} \ Seq \ (inj \ r_1 \ c \ v_1) \ v_2 \\ (5) & inj \ (r_1 \cdot r_2) \ c \ (Left \ (Seq \ v_1 \ v_2)) & \stackrel{\text{def}}{=} \ Seq \ (inj \ r_1 \ c \ v_1) \ v_2 \\ (6) & inj \ (r_1 \cdot r_2) \ c \ (Right \ v_2) & \stackrel{\text{def}}{=} \ Seq \ (mkeps \ r_1) \ (inj \ r_2 \ c \ v_2) \\ (7) & inj \ (r^*) \ c \ (Seq \ v \ (Stars \ vs)) & \stackrel{\text{def}}{=} \ Stars \ (inj \ r \ c \ v :: vs) \\ \end{array}
```

To better understand what is going on in this definition it might be instructive to look first at the three sequence cases (clauses (4) - (6)). In each case we need to construct an "injected value" for $r_1 \cdot r_2$. This must be a value of the form Seq__. Recall the clause of the derivative-function for sequence regular expressions:

$$(r_1 \cdot r_2) \setminus c \stackrel{\text{def}}{=} if \ nullable \ r_1 \ then \ (r_1 \setminus c) \cdot r_2 + (r_2 \setminus c) \ else \ (r_1 \setminus c) \cdot r_2$$

Consider first the *else*-branch where the derivative is $(r_1 \ c) \cdot r_2$. The corresponding value must therefore be of the form $Seq v_1 v_2$, which matches the left-hand side in clause (4) of inj. In the if-branch the derivative is an alternative, namely $(r_1 \setminus c) \cdot r_2 + (r_2 \setminus c)$. This means we either have to consider a Leftor Right-value. In case of the Left-value we know further it must be a value for a sequence regular expression. Therefore the pattern we match in the clause (5) is Left (Seq v_1 v_2), while in (6) it is just Right v_2 . One more interesting point is in the right-hand side of clause (6): since in this case the regular expression r_1 does not "contribute" to matching the string, that means it only matches the empty string, we need to call mkeps in order to construct a value for how r_1 can match this empty string. A similar argument applies for why we can expect in the left-hand side of clause (7) that the value is of the form Seq v (Stars vs)—the derivative of a star is $(r \setminus c) \cdot r^*$. Finally, the reason for why we can ignore the second argument in clause (1) of inj is that it will only ever be called in cases where c = d, but the usual linearity restrictions in patterns do not allow us to build this constraint explicitly into our function definition.⁷

The idea of the inj-function to "inject" a character, say c, into a value can be made precise by the first part of the following lemma, which shows that the underlying string of an injected value has a prepended character c; the second part shows that the underlying string of an mkeps-value is always the empty string (given the regular expression is nullable since otherwise mkeps might not be defined).

Lemma 9.

```
(1) If v : r \setminus c then |inj \ r \ c \ v| = c :: |v|.
(2) If nullable r then |mkeps \ r| = [].
```

Proof. Both properties are by routine inductions: the first one can, for example, be proved by induction over the definition of *derivatives*; the second by an induction on r. There are no interesting cases.

Having defined the mkeps and inj function we can extend Brzozowski's matcher so that a value is constructed (assuming the regular expression matches the string). The clauses of the Sulzmann and Lu lexer are

```
\begin{array}{ll} lexer \ r \ [] & \stackrel{\mathrm{def}}{=} \ if \ nullable \ r \ then \ Some \ (mkeps \ r) \ else \ None \\ lexer \ r \ (c :: s) \stackrel{\mathrm{def}}{=} \ case \ lexer \ (r \backslash c) \ s \ of \\ & None \ \Rightarrow None \\ & | \ Some \ v \Rightarrow Some \ (inj \ r \ c \ v) \end{array}
```

If the regular expression does not match the string, *None* is returned. If the regular expression *does* match the string, then *Some* value is returned. One important virtue of this algorithm is that it can be implemented with ease in any

⁷ Sulzmann and Lu state this clause as inj c c (Empty) $\stackrel{\text{def}}{=}$ Char c, but our deviation

Fig. 2. Our inductive definition of POSIX values.

functional programming language and also in Isabelle/HOL. In the remaining part of this section we prove that this algorithm is correct.

The well-known idea of POSIX matching is informally defined by some rules such as the Longest Match and Priority Rules (see Introduction); as correctly argued in [13], this needs formal specification. Sulzmann and Lu define an "ordering relation" between values and argue that there is a maximum value, as given by the derivative-based algorithm. In contrast, we shall introduce a simple inductive definition that specifies directly what a POSIX value is, incorporating the POSIX-specific choices into the side-conditions of our rules. Our definition is inspired by the matching relation given by Vansummeren [14]. The relation we define is ternary and written as $(s, r) \rightarrow v$, relating strings, regular expressions and values; the inductive rules are given in Figure 2. We can prove that given a string s and regular expression r, the POSIX value v is uniquely determined by $(s, r) \rightarrow v$.

Theorem 1.

(1) If
$$(s, r) \rightarrow v$$
 then $s \in L(r)$ and $|v| = s$.
(2) If $(s, r) \rightarrow v$ and $(s, r) \rightarrow v'$ then $v = v'$.

Proof. Both by induction on the definition of $(s, r) \to v$. The second parts follows by a case analysis of $(s, r) \to v'$ and the first part.

We claim that our $(s, r) \to v$ relation captures the idea behind the four informal POSIX rules shown in the Introduction: Consider for example the rules P+L and P+R where the POSIX value for a string and an alternative regular expression, that is $(s, r_1 + r_2)$, is specified—it is always a *Left*-value, *except* when the string to be matched is not in the language of r_1 ; only then it is a *Right*-value (see the side-condition in P+R). Interesting is also the rule for sequence regular expressions (PS). The first two premises state that v_1 and v_2 are the POSIX

A similar condition is imposed on the POSIX value in the $P\star$ -rule. Also there we want that s_1 is the longest initial split of $s_1 @ s_2$ and furthermore the corresponding value v cannot be flattened to the empty string. In effect, we require that in each "iteration" of the star, some non-empty substring needs to be "chipped" away; only in case of the empty string we accept Stars [] as the POSIX value. Indeed we can show that our POSIX values are lexical values which exclude those Stars that contain subvalues that flatten to the empty string.

Lemma 10. If $(s, r) \rightarrow v$ then $v \in LV r s$.

Proof. By routine induction on
$$(s, r) \to v$$
.

Next is the lemma that shows the function mkeps calculates the POSIX value for the empty string and a nullable regular expression.

Lemma 11. If nullable r then $([], r) \rightarrow mkeps r$.

Proof. By routine induction on r.

The central lemma for our POSIX relation is that the *inj*-function preserves POSIX values.

Lemma 12. If $(s, r \setminus c) \rightarrow v$ then $(c :: s, r) \rightarrow inj \ r \ c \ v$.

Proof. By induction on r. We explain two cases.

- Case $r = r_1 + r_2$. There are two subcases, namely (a) $v = Left \ v'$ and (s, $r_1 \backslash c$) $\rightarrow v'$; and (b) $v = Right \ v'$, $s \notin L(r_1 \backslash c)$ and (s, $r_2 \backslash c$) $\rightarrow v'$. In (a) we know (s, $r_1 \backslash c$) $\rightarrow v'$, from which we can infer (c:: s, r_1) $\rightarrow inj \ r_1 \ c \ v'$ by induction hypothesis and hence (c:: s, $r_1 + r_2$) $\rightarrow inj \ (r_1 + r_2) \ c \ (Left \ v')$ as needed. Similarly in subcase (b) where, however, in addition we have to use Proposition 1(2) in order to infer c:: $s \notin L(r_1)$ from $s \notin L(r_1 \backslash c)$.
- Case $r = r_1 \cdot r_2$. There are three subcases:
 - (a) $v = Left (Seq v_1 v_2)$ and nullable r_1
 - (b) $v = Right v_1 \text{ and } nullable r_1$
 - (c) $v = Seq v_1 v_2 \text{ and } \neg nullable r_1$

For (a) we know $(s_1, r_1 \setminus c) \to v_1$ and $(s_2, r_2) \to v_2$ as well as

$$\nexists s_3 \ s_4.a. \ s_3 \neq [] \land s_3 @ s_4 = s_2 \land s_1 @ s_3 \in L(r_1 \backslash c) \land s_4 \in L(r_2)$$

From the latter we can infer by Proposition 1(2):

$$\nexists s_3 \ s_4.a. \ s_3 \neq [] \land s_3 @ s_4 = s_2 \land c :: s_1 @ s_3 \in L(r_1) \land s_4 \in L(r_2)$$

We can use the induction hypothesis for r_1 to obtain $(c:: s_1, r_1) \to inj r_1 c$ v_1 . Putting this all together allows us to infer $(c:: s_1 @ s_2, r_1 \cdot r_2) \to Seq$ $(inj r_1 c v_1) v_2$. The case (c) is similar.

For (b) we know $(s, r_2 \setminus c) \to v_1$ and $s_1 \otimes s_2 \notin L((r_1 \setminus c) \cdot r_2)$. From the former we have $(c :: s, r_2) \to inj r_2 c v_1$ by induction hypothesis for r_2 . From the latter we can infer

$$\nexists s_3 \ s_4.a. \ s_3 \neq [] \land s_3 @ s_4 = c :: s \land s_3 \in L(r_1) \land s_4 \in L(r_2)$$

By Lemma 11 we know ([], r_1) \rightarrow mkeps r_1 holds. Putting this all together, we can conclude with $(c::s, r_1 \cdot r_2) \rightarrow Seq \ (mkeps \ r_1) \ (inj \ r_2 \ c \ v_1)$, as required.

Finally suppose $r = r_1^*$. This case is very similar to the sequence case, except that we need to also ensure that $|inj \ r_1 \ c \ v_1| \neq []$. This follows from $(c:: s_1, \ r_1) \rightarrow inj \ r_1 \ c \ v_1$ (which in turn follows from $(s_1, \ r_1 \setminus c) \rightarrow v_1$ and the induction hypothesis).

With Lemma 12 in place, it is completely routine to establish that the Sulzmann and Lu lexer satisfies our specification (returning the null value *None* iff the string is not in the language of the regular expression, and returning a unique POSIX value iff the string *is* in the language):

Theorem 2.

- (1) $s \notin L(r)$ if and only if lexer r s = None
- (2) $s \in L(r)$ if and only if $\exists v$. lexer $r s = Some \ v \land (s, r) \rightarrow v$

Proof. By induction on s using Lemma 11 and 12.

In (2) we further know by Theorem 1 that the value returned by the lexer must be unique. A simple corollary of our two theorems is:

Corollary 1

- (1) lexer r s = None if and only if $\nexists v.a.(s, r) \rightarrow v$
- (2) lexer $r s = Some \ v \ if \ and \ only \ if \ (s, r) \rightarrow v$

This concludes our correctness proof. Note that we have not changed the algorithm of Sulzmann and Lu,⁸ but introduced our own specification for what a correct result—a POSIX value—should be. In the next section we show that our specification coincides with another one given by Okui and Suzuki using a different technique.

⁸ All deviations we introduced are harmless.

6 Ordering of Values according to Okui and Suzuki

While in the previous section we have defined POSIX values directly in terms of a ternary relation (see inference rules in Figure 2), Sulzmann and Lu took a different approach in [13]: they introduced an ordering for values and identified POSIX values as the maximal elements. An extended version of [13] is available at the website of its first author; this includes more details of their proofs, but which are evidently not in final form yet. Unfortunately, we were not able to verify claims that their ordering has properties such as being transitive or having maximal elements.

Okui and Suzuki [10,11] described another ordering of values, which they use to establish the correctness of their automata-based algorithm for POSIX matching. Their ordering resembles some aspects of the one given by Sulzmann and Lu, but overall is quite different. To begin with, Okui and Suzuki identify POSIX values as minimal, rather than maximal, elements in their ordering. A more substantial difference is that the ordering by Okui and Suzuki uses positions in order to identify and compare subvalues. Positions are lists of natural numbers. This allows them to quite naturally formalise the Longest Match and Priority rules of the informal POSIX standard. Consider for example the value v

$$v \stackrel{def}{=} Stars [Seq (Char x) (Char y), Char z]$$

At position [0,1] of this value is the subvalue *Char y* and at position [1] the subvalue *Char z*. At the 'root' position, or empty list [], is the whole value v. Positions such as [0,1,0] or [2] are outside of v. If it exists, the subvalue of v at a position p, written $v|_p$, can be recursively defined by

$$\begin{array}{c|cccc} v \downarrow_{[]} & \stackrel{def}{=} v \\ Left \ v \downarrow_{0::ps} & \stackrel{def}{=} v \downarrow_{ps} \\ Right \ v \downarrow_{1::ps} & \stackrel{def}{=} v \downarrow_{ps} \\ Seq \ v_1 \ v_2 \downarrow_{0::ps} & \stackrel{def}{=} v_1 \downarrow_{ps} \\ Seq \ v_1 \ v_2 \downarrow_{1::ps} & \stackrel{def}{=} v_2 \downarrow_{ps} \\ Stars \ vs \downarrow_{n::ps} & \stackrel{def}{=} vs_{[n]} \downarrow_{ps} \end{array}$$

In the last clause we use Isabelle's notation $vs_{[n]}$ for the *n*th element in a list. The set of positions inside a value v, written $Pos\ v$, is given by

```
\begin{array}{lll} Pos \; (Empty) & \stackrel{def}{=} \; \{ [ ] \} \\ Pos \; (Char \; c) & \stackrel{def}{=} \; \{ [ ] \} \\ Pos \; (Left \; v) & \stackrel{def}{=} \; \{ [ ] \} \; \cup \; \{ 0 :: \; ps \; | \; ps \; \in \; Pos \; v \} \\ Pos \; (Right \; v) & \stackrel{def}{=} \; \{ [ ] \} \; \cup \; \{ 1 :: \; ps \; | \; ps \; \in \; Pos \; v \} \\ Pos \; (Seq \; v_1 \; v_2) & \stackrel{def}{=} \; \{ [ ] \} \; \cup \; \{ 0 :: \; ps \; | \; ps \; \in \; Pos \; v_1 \} \; \cup \; \{ 1 :: \; ps \; | \; ps \; \in \; Pos \; v_2 \} \\ Pos \; (Stars \; vs) & \stackrel{def}{=} \; \{ [ ] \} \; \cup \; \{ \cup \; n \; < \; len \; vs \; \{ n :: \; ps \; | \; ps \; \in \; Pos \; v_{[n]} \} ) \end{array}
```

whereby *len* in the last clause stands for the length of a list. Clearly for every position inside a value there exists a subvalue at that position.

To help understanding the ordering of Okui and Suzuki, consider again the earlier value v and compare it with the following w:

$$v \stackrel{def}{=} Stars [Seq (Char x) (Char y), Char z]$$

 $w \stackrel{def}{=} Stars [Char x, Char y, Char z]$

Both values match the string xyz, that means if we flatten these values at their respective root position, we obtain xyz. However, at position $[\theta]$, v matches xy whereas w matches only the shorter x. So according to the Longest Match Rule, we should prefer v, rather than w as POSIX value for string xyz (and corresponding regular expression). In order to formalise this idea, Okui and Suzuki introduce a measure for subvalues at position p, called the norm of v at position p. We can define this measure in Isabelle as an integer as follows

$$||v||_p \stackrel{def}{=} if \ p \in Pos \ v \ then \ len \ |v|_p| \ else - 1$$

where we take the length of the flattened value at position p, provided the position is inside v; if not, then the norm is -1. The default for outside positions is crucial for the POSIX requirement of preferring a *Left*-value over a *Right*-value (if they can match the same string—see the Priority Rule from the Introduction). For this consider

$$v \stackrel{def}{=} Left (Char x)$$
 and $w \stackrel{def}{=} Right (Char x)$

$$\frac{p_1 < p_2}{[] \prec_{lex} p :: ps} \qquad \frac{p_1 < p_2}{p_1 :: ps_1 \prec_{lex} p_2 :: ps_2} \qquad \frac{ps_1 \prec_{lex} ps_2}{p :: ps_1 \prec_{lex} p :: ps_2}$$

With the norm and lexicographic order in place, we can state the key definition of Okui and Suzuki [10]: a value v_1 is *smaller at position p* than v_2 , written $v_1 \prec_p v_2$, if and only if (i) the norm at position p is greater in v_1 (that is the string $|v_1\rangle_p|$ is longer than $|v_2\rangle_p|$) and (ii) all subvalues at positions that are inside v_1 or v_2 and that are lexicographically smaller than p, we have the same norm, namely

$$v_1 \prec_p v_2 \stackrel{def}{=} \begin{cases} (i) & \|v_2\|_p < \|v_1\|_p \text{ and} \\ (ii) & \forall \ q \in Pos \ v_1 \cup Pos \ v_2. \ q \prec_{lex} p \longrightarrow \|v_1\|_q = \|v_2\|_q \end{cases}$$

The position p in this definition acts as the first distinct position of v_1 and v_2 , where both values match strings of different length [10]. Since at p the values v_1 and v_2 match different strings, the ordering is irreflexive. Derived from the definition above are the following two orderings:

$$v_1 \prec v_2 \stackrel{def}{=} \exists p. \ v_1 \prec_p \ v_2$$

 $v_1 \preccurlyeq v_2 \stackrel{def}{=} v_1 \prec v_2 \lor v_1 = v_2$

While we encountered a number of obstacles for establishing properties like transitivity for the ordering of Sulzmann and Lu (and which we failed to overcome), it is relatively straightforward to establish this property for the orderings $_ \prec _$ and $_ \preccurlyeq _$ by Okui and Suzuki.

Lemma 13 (Transitivity). If $v_1 \prec v_2$ and $v_2 \prec v_3$ then $v_1 \prec v_3$.

Proof. From the assumption we obtain two positions p and q, where the values v_1 and v_2 (respectively v_2 and v_3) are 'distinct'. Since \prec_{lex} is trichotomous, we need to consider three cases, namely $p=q, \ p \prec_{lex} q$ and $q \prec_{lex} p$. Let us look at the first case. Clearly $\|v_2\|_p < \|v_1\|_p$ and $\|v_3\|_p < \|v_2\|_p$ imply $\|v_3\|_p < \|v_1\|_p$. It remains to show that for a $p' \in Pos\ v_1 \cup Pos\ v_3$ with $p' \prec_{lex} p$ that $\|v_1\|_{p'} = \|v_3\|_{p'}$ holds. Suppose $p' \in Pos\ v_1$, then we can infer from the first assumption that $\|v_1\|_{p'} = \|v_2\|_{p'}$. But this means that p' must be in $Pos\ v_2$ too (the norm cannot be -1 given $p' \in Pos\ v_1$). Hence we can use the second assumption and infer $\|v_2\|_{p'} = \|v_3\|_{p'}$, which concludes this case with $v_1 \prec v_3$. The reasoning in the other cases is similar.

The proof for \preccurlyeq is similar and omitted. It is also straightforward to show that \prec and \preccurlyeq are partial orders. Okui and Suzuki furthermore show that they are linear orderings for lexical values [10] of a given regular expression and given string, but we have not formalised this in Isabelle. It is not essential for our results. What we are going to show below is that for a given r and s, the orderings have a unique minimal element on the set LV r s, which is the POSIX value we defined in the previous section. We start with two properties that show how the length of a flattened value relates to the \prec -ordering.

Proposition 4.

(1) If $v_1 \prec v_2$ then len $|v_2| \leq len |v_1|$. (2) If $len |v_2| < len |v_1|$ then $v_1 \prec v_2$.

Both properties follow from the definition of the ordering. Note that (2) entails that a value, say v_2 , whose underlying string is a strict prefix of another flattened value, say v_1 , then v_1 must be smaller than v_2 . For our proofs it will be useful to have the following properties—in each case the underlying strings of the compared values are the same:

Proposition 5.

One might prefer that statements (4) and (5) (respectively (6) and (7)) are combined into a single iff-statement (like the ones for Left and Right). Unfortunately this cannot be done easily: such a single statement would require an additional assumption about the two values $Seq\ v_1\ v_2$ and $Seq\ w_1\ w_2$ being inhabited by the same regular expression. The complexity of the proofs involved seems to not justify such a 'cleaner' single statement. The statements given are just the properties that allow us to establish our theorems without any difficulty. The proofs for Proposition 5 are routine.

Next we establish how Okui and Suzuki's orderings relate to our definition of POSIX values. Given a *POSIX* value v_1 for r and s, then any other lexical value v_2 in LV r s is greater or equal than v_1 , namely:

```
Theorem 3. If (s, r) \rightarrow v_1 and v_2 \in LV \ r \ s \ then \ v_1 \leq v_2.
```

Proof. By induction on our POSIX rules. By Theorem 1 and the definition of LV, it is clear that v_1 and v_2 have the same underlying string s. The three base cases are straightforward: for example for $v_1 = Empty$, we have that $v_2 \in LV$ 1 [] must also be of the form $v_2 = Empty$. Therefore we have $v_1 \leq v_2$. The inductive cases for r being of the form $r_1 + r_2$ and $r_1 \cdot r_2$ are as follows:

- Case P+L with (s, r₁ + r₂) → Left w₁: In this case the value v₂ is either of the form Left w₂ or Right w₂. In the latter case we can immediately conclude with v₁ ≤ v₂ since a Left-value with the same underlying string s is always smaller than a Right-value by Proposition 5(1). In the former case we have w₂ ∈ LV r₁ s and can use the induction hypothesis to infer w₁ ≤ w₂. Because w₁ and w₂ have the same underlying string s, we can conclude with Left w₁ ≤ Left w₂ using Proposition 5(2).
- Case P+R with $(s, r_1 + r_2) \to Right \ w_1$: This case similar to the previous case, except that we additionally know $s \notin L(r_1)$. This is needed when v_2 is of the form $Left \ w_2$. Since $|v_2| = |w_2| = s$ and $w_2 : r_1$, we can derive a contradiction for $s \notin L(r_1)$ using Proposition 2. So also in this case $v_1 \preceq v_2$.
- Case PS with $(s_1 @ s_2, r_1 \cdot r_2) \rightarrow Seq \ w_1 \ w_2$: We can assume $v_2 = Seq \ u_1 \ u_2$ with $u_1 : r_1$ and $u_2 : r_2$. We have $s_1 @ s_2 = |u_1| @ |u_2|$. By the side-condition of the PS-rule we know that either $s_1 = |u_1|$ or that $|u_1|$ is a strict prefix of s_1 . In the latter case we can infer $w_1 \prec u_1$ by Proposition 4(2) and from this $v_1 \preccurlyeq v_2$ by Proposition 5(5) (as noted above v_1 and v_2 must have the same underlying string). In the former case we know $u_1 \in LV \ r_1 \ s_1$ and $u_2 \in LV \ r_2 \ s_2$. With this we can use the induction hypotheses to infer $w_1 \preccurlyeq u_1$ and $w_2 \preccurlyeq u_2$. By Proposition 5(4,5) we can again infer $v_1 \preccurlyeq v_2$.

The case for $P\star$ is similar to the PS-case and omitted.

This theorem shows that our POSIX value for a regular expression r and string s is in fact a minimal element of the values in LV r s. By Proposition 4(2) we also know that any value in LV r s', with s' being a strict prefix, cannot be smaller than v_1 . The next theorem shows the opposite—namely any minimal element in LV r s must be a POSIX value. This can be established by induction on r, but the proof can be drastically simplified by using the fact from the previous section about the existence of a POSIX value whenever a string $s \in L(r)$.

Theorem 4. If $v_1 \in LV \ r \ s \ and \ \forall \ v_2 \in LV \ r \ s. \ v_2 \not\prec v_1 \ then \ (s, \ r) \rightarrow v_1.$

Proof. If $v_1 \in LV \ r \ s$ then $s \in L(r)$ by Proposition 2. Hence by Theorem 2(2) there exists a *POSIX* value v_P with $(s, r) \to v_P$ and by Lemma 10 we also have $v_P \in LV \ r \ s$. By Theorem 3 we therefore have $v_P \preccurlyeq v_1$. If $v_P = v_1$ then we are done. Otherwise we have $v_P \prec v_1$, which however contradicts the second assumption about v_1 being the smallest element in $LV \ r \ s$. So we are done in this case too.

From this we can also show that if LV r s is non-empty (or equivalently $s \in L(r)$) then it has a unique minimal element:

Corollary 2. If LV $r s \neq \emptyset$ then $\exists ! vmin. vmin \in LV r s \land (\forall v \in LV r s. vmin \leq v)$.

To sum up, we have shown that the (unique) minimal elements of the ordering by Okui and Suzuki are exactly the *POSIX* values we defined inductively in Section 5. This provides an independent confirmation that our ternary relation formalises the informal POSIX rules.

7 Bitcoded Lexing

Incremental calculation of the value. To simplify the proof we first define the function flex which calculates the "iterated" injection function. With this we can rewrite the lexer as

lexer $r s = (if \ nullable \ (r \setminus s) \ then \ Some \ (flex \ r \ id \ s \ (mkeps \ (r \setminus s))) \ else \ None)$

8 Optimisations

Derivatives as calculated by Brzozowski's method are usually more complex regular expressions than the initial one; the result is that the derivative-based matching and lexing algorithms are often abysmally slow. However, various optimisations are possible, such as the simplifications of $\mathbf{0} + r$, $r + \mathbf{0}$, $\mathbf{1} \cdot r$ and $r \cdot \mathbf{1}$ to r. These simplifications can speed up the algorithms considerably, as noted

in [13]. One of the advantages of having a simple specification and correctness proof is that the latter can be refined to prove the correctness of such simplification steps. While the simplification of regular expressions according to rules like

$$\mathbf{0} + r \Rightarrow r$$
 $r + \mathbf{0} \Rightarrow r$ $\mathbf{1} \cdot r \Rightarrow r$ $r \cdot \mathbf{1} \Rightarrow r$ (2)

is well understood, there is an obstacle with the POSIX value calculation algorithm by Sulzmann and Lu: if we build a derivative regular expression and then simplify it, we will calculate a POSIX value for this simplified derivative regular expression, not for the original (unsimplified) derivative regular expression. Sulzmann and Lu [13] overcome this obstacle by not just calculating a simplified regular expression, but also calculating a rectification function that "repairs" the incorrect value.

The rectification functions can be (slightly clumsily) implemented in Isabelle/HOL as follows using some auxiliary functions:

$$\begin{array}{lll} F_{Right} \, f \, v & \stackrel{\text{def}}{=} \, Right \, (f \, v) \\ F_{Left} \, f \, v & \stackrel{\text{def}}{=} \, Left \, (f \, v) \\ F_{Alt} \, f_1 \, f_2 \, (Right \, v) & \stackrel{\text{def}}{=} \, Right \, (f_2 \, v) \\ F_{Alt} \, f_1 \, f_2 \, (Left \, v) & \stackrel{\text{def}}{=} \, Left \, (f_1 \, v) \\ F_{Seq1} \, f_1 \, f_2 \, v & \stackrel{\text{def}}{=} \, Seq \, (f_1 \, ()) \, (f_2 \, v) \\ F_{Seq2} \, f_1 \, f_2 \, v & \stackrel{\text{def}}{=} \, Seq \, (f_1 \, v) \, (f_2 \, ()) \\ F_{Seq} \, f_1 \, f_2 \, (Seq \, v_1 \, v_2) & \stackrel{\text{def}}{=} \, Seq \, (f_1 \, v_1) \, (f_2 \, v_2) \\ simp_{Alt} \, (\mathbf{0}, \, _) \, (r_2, f_2) & \stackrel{\text{def}}{=} \, (r_2, F_{Right} \, f_2) \\ simp_{Alt} \, (r_1, f_1) \, (\mathbf{0}, \, _) & \stackrel{\text{def}}{=} \, (r_1, F_{Left} \, f_1) \\ simp_{Seq} \, (\mathbf{1}, f_1) \, (r_2, f_2) & \stackrel{\text{def}}{=} \, (r_2, F_{Seq1} \, f_1 \, f_2) \\ simp_{Seq} \, (r_1, f_1) \, (\mathbf{1}, f_2) & \stackrel{\text{def}}{=} \, (r_1, F_{Seq2} \, f_1 \, f_2) \\ simp_{Seq} \, (r_1, f_1) \, (r_2, f_2) & \stackrel{\text{def}}{=} \, (r_1, F_{Seq2} \, f_1 \, f_2) \\ simp_{Seq} \, (r_1, f_1) \, (r_2, f_2) & \stackrel{\text{def}}{=} \, (r_1, F_{Seq2} \, f_1 \, f_2) \\ \end{cases}$$

The functions $simp_{Alt}$ and $simp_{Seq}$ encode the simplification rules in (2) and compose the rectification functions (simplifications can occur deep inside the regular expression). The main simplification function is then

$$simp (r_1 + r_2) \stackrel{\text{def}}{=} simp_{Alt} (simp \ r_1) (simp \ r_2)$$

 $simp (r_1 \cdot r_2) \stackrel{\text{def}}{=} simp_{Seq} (simp \ r_1) (simp \ r_2)$
 $simp \ r \stackrel{\text{def}}{=} (r, id)$

where id stands for the identity function. The function simp returns a simplified regular expression and a corresponding rectification function. Note that we do

not simplify under stars: this seems to slow down the algorithm, rather than speed it up. The optimised lexer is then given by the clauses:

```
lexer^+ r [] \stackrel{\text{def}}{=} if \ nullable \ r \ then \ Some \ (mkeps \ r) \ else \ None
lexer^+ \ r \ (c::s) \stackrel{\text{def}}{=} let \ (r_s, f_r) = simp \ (r \setminus c) \ in
case \ lexer^+ \ r_s \ s \ of
None \Rightarrow None
| \ Some \ v \Rightarrow Some \ (inj \ r \ c \ (f_r \ v))
```

In the second clause we first calculate the derivative $r \setminus c$ and then simpli

Incremental calculation of the value. To simplify the proof we first define the function @{const flex} which calculates the "iterated" injection function. With this we can rewrite the lexer as \begin{center} @{thm lexer | flex} $\Lambda \$ & $\{ thm \ (rhs) \ code.simps(2) \} \setminus \{ thm \ (lhs) \ code.simps(3) \}$ & $\{ dn \}$ & $@\{thm\ (rhs)\ code.simps(3)\}\\ @\{thm\ (lhs)\ code.simps(4)\}\ \&\ \$\dn\$\ \&$ $@\{thm\ (rhs)\ code.simps(4)\}\\ @\{thm\ (lhs)\ code.simps(5)[of\ v_1\ v_2]\} \& $\ dn$$ & $@\{thm\ (rhs)\ code.simps(5)[of\ v_1\ v_2]\}\\ @\{thm\ (lhs)\ code.simps(6)\}\ &$ $\$ & @{thm (rhs) code.simps(6)}\\ @{thm (lhs) code.simps(7)} & \$\$\dn\$ & \emptyset {thm (rhs) code.simps(7)} \end{tabular} \end{center} \begin{center} $\begin{tabular}{lcl} @{term\ areg} & $::=$ & @{term\ AZERO}\\ \ & $\\$ & $@\{term\ AONE\ bs\}\\ \&\ mid\ \&\ @\{term\ ACHAR\ bs\ c\}\\ \&\ mid\$ & $@\{term\ AALT\ bs\ r1\ r2\}\\ \&\ \$\mid\$\ \&\ @\{term\ ASEQ\ bs\ r_1\ r_2\}\\ \&$ $\$ \ mid\$ & @{term ASTAR bs r} \ end{tabular} \ end{center} \ \ begin{center} $\begin{array}{l} \begin{array}{l} \begin{array}{l} \begin{array}{l} \begin{array}{l} \begin{array}{l} \\ \end{array} \end{array} \end{array} \end{array} \end{array}$ intern.simps(1) \\ @ $\{thm\ (lhs)\ intern.simps(2)\}$ & \$\\dn\$ & @ $\{thm\ (rhs)\ intern.simps(2)\}$ or \$\\ tern.simps(2) \\ @{thm (lhs) intern.simps(3)} & \$\dn\$ & @{thm (rhs) intern.simps(3)\\ @ $\{thm\ (lhs)\ intern.simps(4)[of\ r_1\ r_2]\}$ & \$\dn\$ & @ $\{thm\ (lhs)\ intern.simps(4)[of\ r_1\ r_2]\}$ (rhs) $intern.simps(4)[of \ r_1 \ r_2]\}\setminus @\{thm \ (lhs) \ intern.simps(5)[of \ r_1 \ r_2]\} \&$ & $\dots \dots \d$ erase.simps(1) \\ @{thm (lhs) erase.simps(2) [of bs]} & \$\dn\$ & @{thm (rhs)} erase.simps(2)[of bs]\\ @ $\{thm (lhs) erase.simps(3)[of bs]\}$ & \$\dn\$ & @ $\{thm (lhs) erase.simps(3)[of bs]\}$ \\ (rhs) erase.simps(3)[of bs]\\ @{thm (lhs) $erase.simps(4)[of bs r_1 r_2]$ } & \$\dn\$ & $@\{thm\ (rhs)\ erase.simps(4)[of\ bs\ r_1\ r_2]\}\\ @\{thm\ (lhs)\ erase.simps(5)[of\ bs\ r_1\ r_2]\}\$ bs r_1 r_2]} & \$\\dn\$ & @{thm (rhs) erase.simps(5)[of bs r_1 r_2]}\\ @{thm (lhs) erase.simps(6)[of bs] & \dn & @{thm (rhs) erase.simps(6)[of bs]}\\ $\end{tabular} \end{center} Some simple facts about erase \end{lemma} \mbox{} \$ $\begin{array}{l} \begin{array}{l} \begin{array}{l} \begin{array}{l} \begin{array}{l} \begin{array}{l} \\ \end{array} \end{array} \end{array} \end{array} \end{array}$ bnullable.simps(1) \\ @{thm (lhs) bnullable.simps(2)} & \$\dn\$ & @{thm (rhs)} bnullable.simps(2)\\ @{thm (lhs) bnullable.simps(3)} & \$\dn\$ & @{thm (rhs)} bnullable.simps(3) \\ @{thm (lhs) bnullable.simps(4)[of bs r_1 r_2]} & \$\dn\$ &

section Optimisations

Derivatives as calculated by $\Brz's$ method are usually more complex regular expressions than the initial one; the result is that the derivative-based matching and lexing algorithms are often abysmally slow. However, various optimisations are possible, such as the simplifications of $\{term\ ALT\ ZERO\ r\}$, $\{\text{term ALT } r \text{ ZERO}\}, \{\text{term SEQ ONE } r\} \text{ and } \{\text{term SEQ } r \text{ ONE}\} \text{ to}$ $\{ellet \{r\}\}$. These simplifications can speed up the algorithms considerably, as noted in $\cite{Sulzmann2014}$. One of the advantages of having a simple specification and correctness proof is that the latter can be refined to prove the correctness of such simplification steps. While the simplification of regular expressions $according to rules like \setminus begin\{equation\} \setminus label\{Simpl\} \setminus begin\{array\}\{lcllcllcllcl\}$ $@\{term\ ALT\ ZERO\ r\} \& \Leftrightarrow \& @\{term\ r\} \setminus hspace\{8mm\}\% \setminus @\{term\ ALT\ r\}$ & $@\{term\ r\}\ \backslash hspace\{8mm\}\%\backslash \ @\{term\ SEQ\ r\ ONE\}\ \& \iff \& @\{term\ r\}$ r} \end{array} \end{equation} \noindent is well understood, there is an obstacle with the POSIX value calculation algorithm by Sulzmann and Lu: if we build a derivative regular expression and then simplify it, we will calculate a POSIX value for this simplified derivative regular expression, $\{not\}$ for the original (unsimplified) derivative regular expression. Sulzmann and Lu $\cite{Sulzmann2014}$ overcome this obstacle by not just calculating a simplified regular expression, but also calculating a $emph{rectification function}$ that "repairs" the incorrect value. The rectification functions can be (slightly clumsily) implemented in Isabelle/HOL as follows using some auxiliary func-& $\d \$ & $\langle Left (f v) \rangle \setminus @\{thm (lhs) F_ALT.simps(1)\} \& \\ dn \& \langle Right (f_2 v) \rangle \setminus \\ equiv ALT.simps(1)\} \& \\ equiv Algebra (f_2 v) \otimes \\ equiv Algebra (f_2 v$

 $@\{thm\ (lhs)\ F_ALT.simps(2)\} \& \$\dn\$ \& \land Left\ (f_1\ v) \land \ \ @\{thm\ (lhs)\}$ $F_SEQ1.simps(1)$ & \dn & $\ensuremath{\cline{CP}} dn$ & $\$ & $\d \$ & & \d \ & $\d \$ & & \d \ & $\d \$ & $\d \$ & $\langle Seq\ (f_1\ v_1)\ (f_2\ v_2)\rangle \backslash medskip \backslash \ \% \backslash end\{tabular\}\ \% \ \% \backslash begin\{tabular\}\{lcl\}$ $@\{term\ simp_ALT\ (ZERO,\ DUMMY)\ (r_2,\ f_2)\} \& \$\backslash dn\$ \& @\{term\ (r_2,\ f_3)\}$ $F_RIGHT f_2$ \\ @ $\{term simp_ALT (r_1, f_1) (ZERO, DUMMY)\} & $\dn$$ & @ $\{term\ (r_1,\ F_LEFT\ f_1)\}\$ @ $\{term\ simp_ALT\ (r_1,\ f_1)\ (r_2,\ f_2)\}$ & $\Lambda \$ & $\{term\ (ALT\ r_1\ r_2,\ F_ALT\ f_1\ f_2)\}\setminus \{term\ simp_SEQ\ (ONE,\ simp_SEQ\ (ONE$ f_1) (r_2, f_2) } & \$\dn\$ & @{term $(r_2, F__SEQ1 f_1 f_2)}\\ @{term simp_SEQ}$ $(r_1, f_1) (ONE, f_2)$ & \$\dn\$ & @{term $(r_1, F_{__}SEQ2 f_1 f_2)$ }\\ @{term $simp_SEQ\ (r_1, f_1)\ (r_2, f_2)$ & \$\dn\$ & @{term} (SEQ\ r_1\ r_2, F_SEQ\ f_1\) $\langle simp_{Seq} \rangle$ encode the simplification rules in $\backslash eqref\{Simpl\}$ and compose the rectification functions (simplifications can occur deep inside the regular expression). The main simplification function is then $\begin{center} \begin{center} \cline{center} \begin{center} \cline{center} \cline{center} \end{center} \end{center}$ $@\{term\ simp\ (ALT\ r_1\ r_2)\} \& \$\backslash dn\$ \& @\{term\ simp__ALT\ (simp\ r_1)\ (simp\ r_2)\}$ r_2)}\\ @{term simp (SEQ r_1 r_2)} & \$\dn\$ & @{term simp__SEQ (simp r_1) $(simp\ r_2)$ \\ @ $\{term\ simp\ r\}$ & \$\\dn\$ & @ $\{term\ (r,\ id)\}$ \\ \\end $\{tabular\}$ $\ensuremath{\setminus} end\{center\}$ \noindent where $@\{term\ id\}$ stands for the identity function. The function @{const simp} returns a simplified regular expression and a corresponding rectification function. Note that we do not simplify under stars: this seems to slow down the algorithm, rather than speed it up. The optimised lexer is then given by the clauses: $\left(\frac{center}{center}\right)$ (lhs) slexer.simps(1) & \dots \delta @{thm (rhs) slexer.simps(1)}\\ @{thm (lhs) slexer.simps(2) & \$\dn\$ & \left((r_s, f_r) = simp (r \)\$\backslash\$\left(c) in\\\ $\langle \Rightarrow \rangle \otimes \{term\ None\} \setminus \& \& \$ | \$ \otimes \{term\ Some\ v\} \langle \Rightarrow \rangle \langle Some\ (inj\ r\ c\ (f_r\ v)) \rangle$ $\ensuremath{\setminus} end\{tabular\} \ensuremath{\setminus} end\{center\} \ensuremath{\setminus} no indent\ In\ the\ second\ clause\ we\ first\ calcu$ late the derivative $@\{term\ der\ c\ r\}$ and then simplify the result. This gives us a simplified derivative $\langle r_s \rangle$ and a rectification function $\langle f_r \rangle$. The lexer is then recursively called with the simplified derivative, but before we inject the character $@\{term\ c\}$ into the value $@\{term\ v\}$, we need to rectify $@\{term\ v\}$ (that is construct $\mathfrak{Q}\{term\ f_r\ v\}$). Before we can establish the correctness of @{term slexer}, we need to show that simplification preserves the language and simplification preserves our POSIX relation once the value is rectified (recall @{const simp} generates a (regular expression, rectification function) pair): $\begin{lemma} \mbox{}$ & $@\{thm L__fst__simp[symmetric]\} \setminus (2) & @\{thm[mode=IfThen] Posix__simp\}$ $\end{tabular} \end{lemma} \end{proof} Both are by induction on \end{r}. There$ is no interesting case for the first statement. For the second statement, of interest are the $\mathfrak{Q}\{term\ r = ALT\ r_1\ r_2\}$ and $\mathfrak{Q}\{term\ r = SEQ\ r_1\ r_2\}$ cases. In each case we have to analyse four subcases whether $\{term\ fst\ (simp\ r_1)\}\$ and $\{term\ fst\ (simp\ r_1)\}\$ $fst\ (simp\ r_2)\}\ equals\ @\{const\ ZERO\}\ (respectively\ @\{const\ ONE\}).$ For example for $\mathfrak{Q}\{term\ r=ALT\ r_1\ r_2\}$, consider the subcase $\mathfrak{Q}\{term\ fst\ (simp\ r_1)=1\}$ ZERO and @{term fst (simp r_2) \neq ZERO}. By assumption we know @{term s

 \in fst $(simp\ (ALT\ r_1\ r_2)) \to v$. From this we can infer $@\{term\ s \in fst\ (simp\ r_1)\}$ $r_2) \rightarrow v$ and by IH also (*) $\mathfrak{Q}\{term\ s \in r_2 \rightarrow (snd\ (simp\ r_2)\ v)\}$. Given $\mathfrak{Q}\{term\ fst\ (simp\ r_1)=ZERO\}\ we\ know\ \mathfrak{Q}\{term\ L\ (fst\ (simp\ r_1))=\{\}\}.\ By$ the first statement $@\{term\ L\ r_1\}$ is the empty set, meaning (**) $@\{term\ s \notin L$ r_1 . Taking (*) and (**) together gives by the \mbox{ $\langle P+R \rangle}-rule @\{term s$ $\in ALT \ r_1 \ r_2 \to Right \ (sind \ (simp \ r_2) \ v) \}.$ In turn this gives $@\{term \ s \in ALT \ r_1 \ r_2 \to Right \ (sind \ (simp \ r_2) \ v) \}.$ $r_1 r_2 \rightarrow snd (simp (ALT r_1 r_2)) v$ as we need to show. The other cases are wardly that the optimised lexer produces the expected result: \begin{theorem} $@\{thm\ slexer_correctness\} \setminus end\{theorem\} \setminus begin\{proof\}\ By\ induction\ on$ $@\{term\ s\}\ generalising\ over\ @\{term\ r\}.$ The case $@\{term\ []\}\ is\ trivial.$ For the cons-case suppose the string is of the form $@\{term\ c \# s\}$. By induction hypothesis we know $\{term\ slexer\ r\ s = lexer\ r\ s\}\ holds$ for all $\{term\ r\}$ (in particular for $@\{term\ r\}$ being the derivative $@\{term\ der\ c\ r\}$). Let $@\{term\ r_s\}$ be the simplified derivative regular expression, that is @{term fst (simp (der c r))}, and $@\{term f_r\}$ be the rectification function, that is $@\{term snd (simp f_r)\}$ $(der\ c\ r)$. We distinguish the cases whether (*) @ $\{term\ s\in L\ (der\ c\ r)\}$ or not. In the first case we have by Theorem $^{\sim} \operatorname{ref}\{lexercorrect\}(2)$ a value $\{existing \{term\ v\} \ so\ that\ \{existing \{term\ lexer\ (der\ c\ r)\ s=Some\ v\}\ and\ \{term\ s\in\ der\ existing \{term\ se\ existing \{term\ se\ existing \{term\ s\in\ der\ existing \{term\ se\ existing \{term\ existing \{term\ se\ existing \{term\ se\ existing \{term\ exist$ $(c \ r \rightarrow v) \ hold. \ By \ Lemma^{\ } \ ref\{slexeraux\}(1) \ we \ can \ also \ infer \ from^{\ }(*) \ that$ $\{existing \{term \ s \in L \ r_s\} \ holds. \ Hence we know by Theorem \ \ ref\{exercorrect\}(2)\}$ that there exists a $@\{term\ v'\}\ with\ @\{term\ lexer\ r_s\ s=Some\ v'\}\ and\ @\{term\ v'\}\ and\ option of the exists a option of the exi$ $s \in r_s \to v'$. From the latter we know by Lemma~\ref{slexeraux}(2) that $\{erm s \in der \ c \ r \rightarrow (f_r \ v')\}\ holds.$ By the uniqueness of the POSIX relation (Theorem $^{\sim}$ \ref{posixdeterm}) we can infer that @{term v} is equal to @{term $f_r \ v'\} ---t$ that is the rectification function applied to $\{v'\}$ produces the original $@\{term\ v\}$. Now the case follows by the definitions of $@\{const\ lexer\}$ and $\mathfrak{Q}\{const\ slexer\}$. In the second case where $\mathfrak{Q}\{term\ s\notin L\ (der\ c\ r)\}$ we have that $@\{term\ lexer\ (der\ c\ r)\ s = None\}\ by\ Theorem^{\ ref}\{lexercorrect\}(1).$ We also know by Lemma $\sim \text{ref}\{slexeraux\}(1) \text{ that } @\{term \ s \notin L \ r_s\}.$ Hence $\{\text{term lexer } r_s \text{ } s = \text{None}\}\$ by $\text{Theorem}^{\sim} \setminus \text{ref}\{\text{lexercorrect}\}(1) \text{ and by IH then}$ also $\mathfrak{Q}\{\text{term slexer } r_s \ s = \text{None}\}$. With this we can conclude in this case too.\qed $\ensuremath{\backslash} end\{proof\}$ fy the result. This gives us a simplified derivative r_s and a rectification function f_r . The lexer is then recursively called with the simplified derivative, but before we inject the character c into the value v, we need to rectify v (that is construct f_r v). Before we can establish the correctness of $lexer^+$, we need to show that simplification preserves the language and simplification preserves our POSIX relation once the value is rectified (recall simp generates a (regular expression, rectification function) pair):

Lemma 14.

```
(1) L(fst\ (simp\ r)) = L(r)
(2) If (s, fst\ (simp\ r)) \to v then (s, r) \to snd\ (simp\ r)\ v.
```

Proof. Both are by induction on r. There is no interesting case for the first statement. For the second statement, of interest are the $r=r_1+r_2$ and $r=r_1\cdot r_2$ cases. In each case we have to analyse four subcases whether fst (simp

 r_1) and fst ($simp\ r_2$) equals $\mathbf{0}$ (respectively $\mathbf{1}$). For example for $r=r_1+r_2$, consider the subcase fst ($simp\ r_1$) = $\mathbf{0}$ and fst ($simp\ r_2$) $\neq \mathbf{0}$. By assumption we know (s, fst ($simp\ (r_1+r_2)$)) $\to v$. From this we can infer (s, fst ($simp\ r_2$)) $\to v$ and by IH also (*) (s, r_2) $\to snd$ ($simp\ r_2$) v. Given fst ($simp\ r_1$) = $\mathbf{0}$ we know $L(fst\ (simp\ r_1)) = \varnothing$. By the first statement $L(r_1)$ is the empty set, meaning (**) $s \notin L(r_1)$. Taking (*) and (**) together gives by the P+R-rule (s, r_1+r_2) $\to Right$ ($snd\ (simp\ r_2)\ v$). In turn this gives (s, r_1+r_2) $\to snd$ ($simp\ (r_1+r_2)$) v as we need to show. The other cases are similar.

We can now prove relatively straightforwardly that the optimised lexer produces the expected result:

Theorem 5. $lexer^+ r s = lexer r s$

Proof. By induction on s generalising over r. The case [] is trivial. For the conscase suppose the string is of the form c::s. By induction hypothesis we know $lexer^+$ r s = lexer r s holds for all r (in particular for r being the derivative $r \setminus c$). Let r_s be the simplified derivative regular expression, that is fst (simp $(r \setminus c)$), and f_r be the rectification function, that is snd (simp $(r \setminus c)$). We distinguish the cases whether (*) s \in $L(r \setminus c)$ or not. In the first case we have by Theorem 2(2) a value v so that lexer $(r \setminus c)$ s = Some v and $(s, r \setminus c) \rightarrow v$ hold. By Lemma 14(1) we can also infer from (*) that $s \in L(r_s)$ holds. Hence we know by Theorem 2(2) that there exists a v' with lexer r_s s = Some v' and $(s, r_s) \rightarrow v'$. From the latter we know by Lemma 14(2) that $(s, r \setminus c) \rightarrow f_r$ v' holds. By the uniqueness of the POSIX relation (Theorem 1) we can infer that v is equal to f_r v'—that is the rectification function applied to v' produces the original v. Now the case follows by the definitions of lexer and $lexer^+$.

In the second case where $s \notin L(r \setminus c)$ we have that $lexer(r \setminus c)$ s = None by Theorem 2(1). We also know by Lemma 14(1) that $s \notin L(r_s)$. Hence $lexer r_s s = None$ by Theorem 2(1) and by IH then also $lexer^+ r_s s = None$. With this we can conclude in this case too.

9 HERE

Lemma 15. If $v:(r^{\downarrow})\backslash c$ then retrieve $(r\backslash c)$ $v=retrieve\ r\ (inj\ (r^{\downarrow})\ c\ v)$.

Proof. By induction on the definition of r^{\downarrow} . The cases for rule 1) and 2) are straightforward as $\mathbf{0} \setminus c$ and $\mathbf{1} \setminus c$ are both equal to $\mathbf{0}$. This means $v:\mathbf{0}$ cannot hold. Similarly in case of rule 3) where r is of the form ACHAR d with c=d. Then by assumption we know $v:\mathbf{1}$, which implies v=Empty. The equation follows by simplification of left- and right-hand side. In case $c \neq d$ we have again $v:\mathbf{0}$, which cannot hold.

For rule 4a) we have again $v:\mathbf{0}.$ The property holds by IH for rule 4b). The induction hypothesis is

retrieve
$$(r \backslash c)$$
 $v = retrieve \ r \ (inj \ (r^{\downarrow}) \ c \ v)$

which is what left- and right-hand side simplify to. The slightly more interesting case is for 4c). By assumption we have $v:((r_1^{\downarrow})\backslash c)+(((AALTs\ bs\ (r_2::rs))^{\downarrow})\backslash c)$. This means we have either (*) $v1:(r_1^{\downarrow})\backslash c$ with $v=Left\ v1$ or (**) $v2:((AALTs\ bs\ (r_2::rs))^{\downarrow})\backslash c$ with $v=Right\ v2$. The former case is straightforward by simplification. The second case is ...TBD.

Rule 5) TBD.

Finally for rule 6) the reasoning is as follows: By assumption we have $v:((r^{\downarrow})\backslash c)\cdot (r^{\downarrow})^{\star}$. This means we also have $v=Seq\ v1\ v2,\ v1:(r^{\downarrow})\backslash c$ and $v2=Stars\ vs$. We want to prove

retrieve (ASEQ bs (fuse
$$[Z]$$
 $(r \backslash c)$) (ASTAR $[]$ r)) v (3)

= retrieve (ASTAR bs r) (inj
$$((r^{\downarrow})^{\star})$$
 c v) (4)

The right-hand side *inj*-expression is equal to $Stars\ (inj\ (r^{\downarrow})\ c\ v1::vs)$, which means the retrieve-expression simplifies to

bs @
$$[Z]$$
 @ retrieve r (inj (r^{\downarrow}) c $v1$) @ retrieve $(ASTAR [] r)$ $(Stars vs)$

The left-hand side (3) above simplifies to

bs @ retrieve (fuse
$$[Z]$$
 $(r \setminus c)$) v1 @ retrieve (ASTAR $[]$ r) (Stars vs)

We can move out the fuse [Z] and then use the IH to show that left-hand side and right-hand side are equal. This completes the proof.
