

## Core Part 2 (Scala, 1.5 Marks)

*“What one programmer can do in one month,  
two programmers can do in two months.”*

— Frederick P. Brooks (author of *The Mythical Man-Month*)

### Important

- Make sure the files you submit can be processed by just calling `scala compile <<filename.scala>>` on the command line.<sup>1</sup> Use the template files provided and do not make any changes to arguments of functions or to any types. You are free to implement any auxiliary function you might need.
- **Do not leave any test cases running in your code because this might slow down your program!** Comment out test cases before submission, otherwise you might hit a time-out.
- Do not use any mutable data structures in your submissions! They are not needed. This means you cannot create new `Arrays` or `ListBuffers`, for example.
- Do not use `return` in your code! It has a different meaning in Scala than in Java. It changes the meaning of your program, and you should never use it.
- Do not use `var`! This declares a mutable variable. Only use `val`!
- Do not use any parallel collections! No `.par` therefore! Our testing and marking infrastructure is not set up for it.

Also note that the running time of each part will be restricted to a maximum of 30 seconds on my laptop.

### Disclaimer

It should be understood that the work you submit represents your **own** effort! You have implemented the code entirely on your own. You have not copied from anyone else. Do not be tempted to ask Copilot for help or do any other AI-shenanigans like this! An exception is the Scala code I showed during the lectures or uploaded to KEATS, which you can freely use.

---

<sup>1</sup>All major OSes, including Windows, have a command line. So there is no good reason to not download scala, install it and run it on your own computer. Just do it!

## Reference Implementation

Like the C++ part, the Scala part works like this: you push your files to GitHub and receive (after sometimes a long delay) some automated feedback. In the end we will take a snapshot of the submitted files and apply an automated marking script to them.

In addition, the Scala part comes with reference implementations in form of jar-files. This allows you to run any test cases on your own computer. For example you can call `scala` on the command line with the option `--extra-jars docdiff.jar` and then query any function from the template file. Say you want to find out what the function `occurrences` produces: for this you just need to prefix it with the object name `C2`. If you want to find out what these functions produce for the list `List("a", "b", "b")`, you would type something like:

```
$ scala --extra-jars docdiff.jar

scala> C2.occurrences(List("a", "b", "b"))
...
```

## Hints

**For the Core Part 2:** useful operations involving regular expressions:

```
reg.findAllIn(s).toList
```

finds all substrings in `s` according to a regular regular expression `reg`; useful list operations: `.distinct` removing duplicates from a list, `.count` counts the number of elements in a list that satisfy some condition, `.toMap` transfers a list of pairs into a `Map`, `.sum` adds up a list of integers, `.max` calculates the maximum of a list.

## Core Part 2 (1.5 Marks, file docdiff.scala)

It seems plagiarism—stealing and submitting someone else’s code—is a serious problem at other universities.<sup>2</sup> Detecting such plagiarism is time-consuming and disheartening for lecturers at those universities. To aid these poor souls, let’s implement in this part a program that determines the similarity between two documents (be they source code or texts in English). A document will be represented as a list of strings.

### Tasks

- (1) Implement a function that ‘cleans’ a string by finding all (proper) words in the string. For this use the regular expression `\w+` for recognising words and the library function `findAllIn`. The function should return a document (a list of strings). [0.25 Marks]
- (2) In order to compute the overlap between two documents, we associate each document with a `Map`. This `Map` represents the strings in a document and how many times these strings occur in the document. A simple (though slightly inefficient) method for counting the number of string-occurrences in a document is as follows: remove all duplicates from the document; for each of these (unique) strings, count how many times they occur in the original document. Return a `Map` associating strings with occurrences. For example

```
occurrences(List("a", "b", "b", "c", "d"))
```

produces `Map(a -> 1, b -> 2, c -> 1, d -> 1)` and

```
occurrences(List("d", "b", "d", "b", "d"))
```

produces `Map(d -> 3, b -> 2)`. [0.5 Marks]

- (3) You can think of the `Maps` calculated under (2) as memory-efficient representations of sparse “vectors”. In this subtask you need to implement the *product* of two such vectors, sometimes also called *dot product* of two vectors.<sup>3</sup>

For this dot product, implement a function that takes two documents (`List[String]`) as arguments. The function first calculates the (unique) strings in both. For each string, it multiplies the corresponding occurrences in each document. If a string does not occur in one of the documents, then the product for this string is zero. At the end you need to

---

<sup>2</sup>Surely, King’s students, after all their instructions and warnings, would never commit such an offence. Yes?

<sup>3</sup>[https://en.wikipedia.org/wiki/Dot\\_product](https://en.wikipedia.org/wiki/Dot_product)

add up all products. For the two documents in (2) the dot product is 7, because

$$\underbrace{1 * 0}_{\text{"a"}} + \underbrace{2 * 2}_{\text{"b"}} + \underbrace{1 * 0}_{\text{"c"}} + \underbrace{1 * 3}_{\text{"d"}} = 7$$

[0.5 Marks]

- (4) Implement first a function that calculates the overlap between two documents, say  $d_1$  and  $d_2$ , according to the formula

$$\text{overlap}(d_1, d_2) = \frac{d_1 \cdot d_2}{\max(d_1^2, d_2^2)}$$

where  $d_1^2$  means  $d_1 \cdot d_1$  and so on. You can expect this function to return a `Double` between 0 and 1. The overlap between the lists in Task (2) is 0.5384615384615384.

Second, implement a function that calculates the similarity of two strings, by first extracting the substrings using the `clean` function from (1) and then calculating the overlap of the resulting documents.
