1 Direction regular language \Rightarrow finite partition

1.1 The scheme

The following convenient notation $x \approx Lang\ y$ means: string x and y are equivalent with respect to language Lang.

definition

```
str\text{-}eq :: string \Rightarrow lang \Rightarrow string \Rightarrow bool (- \approx -)
where
x \approx Lang \ y \equiv (x, \ y) \in (\approx Lang)
```

The main lemma (rexp-imp-finite) is proved by a structural induction over regular expressions. While base cases (cases for NULL, EMPTY, CHAR) are quite straight forward, the inductive cases are rather involved. What we have when starting to prove these inductive case is that the partitions induced by the componet language are finite. The basic idea to show the finiteness of the partition induced by the composite language is to attach a tag tag(x) to every string x. The tags are made of equivalent classes from

the component partitions. Let tag be the tagging function and Lang be the composite language, it can be proved that if strings with the same tag are equivalent with respect to Lang, expressed as:

$$taq(x) = taq(y) \Longrightarrow x \approx Lanq y$$

then the partition induced by *Lang* must be finite. There are two arguments for this. The first goes as the following:

- 1. First, the tagging function tag induces an equivalent relation (=tag=) (definition of f-eq-rel and lemma equiv-f-eq-rel).
- 2. It is shown that: if the range of tag (denoted range(tag)) is finite, the partition given rise by (=tag=) is finite (lemma finite-eq-f-rel). Since tags are made from equivalent classes from component partitions, and the inductive hypothesis ensures the finiteness of these partitions, it is not difficult to prove the finiteness of range(tag).
- 3. It is proved that if equivalent relation R1 is more refined than R2 (expressed as $R1 \subseteq R2$), and the partition induced by R1 is finite, then the partition induced by R2 is finite as well (lemma refined-partition-finite).
- 4. The injectivity assumption $tag(x) = tag(y) \Longrightarrow x \approx Lang y$ implies that (=tag=) is more refined than $(\approx Lang)$.
- 5. Combining the points above, we have: the partition induced by language *Lang* is finite (lemma *tag-finite-imageD*).

A more concise, but less intelligible argument for tag-finite-imageD is given as the following. The basic idea is still using standard library lemma finite-imageD:

$$\llbracket finite\ (f\ 'A);\ inj\text{-on}\ f\ A\rrbracket \Longrightarrow finite\ A$$

which says: if the image of injective function f over set A is finite, then A must be finte, as we did in the lemmas above.

```

1.2 The proof

Each case is given in a separate section, as well as the final main lemma. Detailed explainations accompanied by illustrations are given for non-trivial cases

For ever inductive case, there are two tasks, the easier one is to show the range finiteness of of the tagging function based on the finiteness of component partitions, the difficult one is to show that strings with the same tag are equivalent with respect to the composite language. Suppose the composite language be Lang, tagging function be tag, it amounts to show:

$$tag(x) = tag(y) \Longrightarrow x \approx Lang y$$

expanding the definition of $\approx Lang$, it amounts to show:

$$taq(x) = taq(y) \Longrightarrow (\forall z. \ x@z \in Lanq \longleftrightarrow y@z \in Lanq)$$

Because the assumed tag equlity tag(x) = tag(y) is symmetric, it is sufficient to show just one direction:

$$\bigwedge \ x \ y \ z. \ [\![tag(x) = tag(y); \ x@z \in Lang]\!] \Longrightarrow y@z \in Lang$$

This is the pattern followed by every inductive case.

1.2.5 The inductive case for SEQ

For case SEQ, the language L is L_1 ;; L_2 . Given $x @ z \in L_1$;; L_2 , according to the defintion of L_1 ;; L_2 , string x @ z can be splitted with the prefix in

 L_1 and suffix in L_2 . The split point can either be in x (as shown in Fig. 1(a)), or in z (as shown in Fig. 1(c)). Whichever way it goes, the structure on x @ z cn be transfered faithfully onto y @ z (as shown in Fig. 1(b) and 1(d)) with the help of the assumed tag equality. The following tag function tag-str-SEQ is such designed to facilitate such transfers and lemma tag-str-SEQ-injI formalizes the informal argument above. The details of structure transfer will be given their.

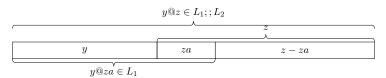

(a) First possible way to split x@z

(b) Transferred structure corresponding to the first way of splitting

(c) The second possible way to split x@z

(d) Transferred structure corresponding to the second way of splitting

Figure 1: The case for SEQ

definition

```
tag\text{-}str\text{-}SEQ :: lang \Rightarrow lang \Rightarrow string \Rightarrow (lang \times lang \ set)
where
tag\text{-}str\text{-}SEQ \ L1 \ L2 =
(\lambda x. \ (\approx L1 \ `` \{x\}, \{(\approx L2 \ `` \{x - xa\}) \mid xa. \ xa \leq x \land xa \in L1\}))
```

The following is a techical lemma which helps to split the $x @ z \in L_1$;; L_2 mentioned above.

```
lemma append-seq-elim: assumes x @ y \in L_1 ;; L_2
```

```
shows (\exists xa \leq x. xa \in L_1 \land (x - xa) @ y \in L_2) \lor
         (\exists ya \leq y. (x @ ya) \in L_1 \land (y - ya) \in L_2)
proof-
  from assms obtain s_1 s_2
   where eq-xys: x @ y = s_1 @ s_2
   and in-seq: s_1 \in L_1 \land s_2 \in L_2
   by (auto simp:Seq-def)
  from app-eq-dest [OF eq-xys]
  have
   (x \le s_1 \land (s_1 - x) @ s_2 = y) \lor (s_1 \le x \land (x - s_1) @ y = s_2)
             (is ?Split1 \lor ?Split2).
 moreover have ?Split1 \Longrightarrow \exists ya \leq y. (x @ ya) \in L_1 \land (y - ya) \in L_2
   using in-seq by (rule-tac x = s_1 - x in exI, auto elim:prefixE)
 moreover have ?Split2 \Longrightarrow \exists xa \leq x. xa \in L_1 \land (x - xa) @ y \in L_2
   using in-seq by (rule-tac x = s_1 in exI, auto)
 ultimately show ?thesis by blast
qed
lemma tag-str-SEQ-injI:
 fixes v w
 assumes eq-tag: tag-str-SEQ L_1 L_2 v = tag-str-SEQ L_1 L_2 w
 shows v \approx (L_1 ;; L_2) w
proof-
   — As explained before, a pattern for just one direction needs to be dealt with:
  \{ \mathbf{fix} \ x \ y \ z \}
   assume xz-in-seq: x @ z \in L_1 ;; L_2
   and tag-xy: tag-str-SEQ L_1 L_2 x = tag-str-SEQ L_1 L_2 y
   have 0 \ z \in L_1 ;; L_2
   proof-
       - There are two ways to split x@z:
     from append-seq-elim [OF xz-in-seq]
     have (\exists xa \leq x. xa \in L_1 \land (x - xa) @ z \in L_2) \lor
             (\exists za \leq z. (x @ za) \in L_1 \land (z - za) \in L_2).
     — It can be shown that ?thesis holds in either case:
     moreover {
       — The case for the first split:
       assume h1: xa \leq x and h2: xa \in L_1 and h3: (x - xa) @ z \in L_2
          The following subgoal implements the structure transfer:
       obtain ya
         where ya \leq y
         and ya \in L_1
         and (y - ya) @ z \in L_2
       proof -
          By expanding the definition of
       — tag-str-SEQ L_1 L_2 x = tag-str-SEQ L_1 L_2 y
          and extracting the second compoent, we get:
```

```
have \{ \approx L_2 \text{ "} \{x - xa\} \mid xa. \ xa \leq x \land xa \in L_1 \} =
                \{\approx L_2 \text{ "} \{y-ya\} \mid ya.\ ya \leq y \land ya \in L_1\} \text{ (is ?Left} = ?Right)
          using tag-xy unfolding tag-str-SEQ-def by simp
          — Since xa \leq x and xa \in L_1 hold, it is not difficult to show:
        moreover have \approx L_2 " \{x - xa\} \in ?Left \text{ using } h1 \ h2 \text{ by } auto
             Through tag equality, equivalent class \approx L_2 " \{x - xa\}
             also belongs to the ?Right:
        ultimately have \approx L_2 " \{x - xa\} \in ?Right  by simp
          — From this, the counterpart of xa in y is obtained:
        then obtain ya
          where eq-xya: \approx L_2 " \{x - xa\} = \approx L_2 " \{y - ya\}
          and pref-ya: ya \leq y and ya-in: ya \in L_1
          by simp blast
        — It can be proved that ya has the desired property:
        have (y - ya)@z \in L_2
        proof -
          from eq-xya have (x - xa) \approx L_2 (y - ya)
            unfolding Image-def str-eq-rel-def str-eq-def by auto
          with h3 show ?thesis unfolding str-eq-rel-def str-eq-def by simp
        ged
          – Now, ya has all properties to be a qualified candidate:
        with pref-ya ya-in
        show ?thesis using prems by blast
         — From the properties of ya, y @ z \in L_1;; L_2 is derived easily.
       hence y @ z \in L_1 ;; L_2 by (erule-tac prefixE, auto simp:Seq-def)
     } moreover {
        - The other case is even more simpler:
       assume h1: za \leq z and h2: (x @ za) \in L_1 and h3: z - za \in L_2
       have y @ za \in L_1
       proof-
        have \approx L_1 " \{x\} = \approx L_1 " \{y\}
          using tag-xy unfolding tag-str-SEQ-def by simp
        with h2 show ?thesis
          unfolding Image-def str-eq-rel-def str-eq-def by auto
       with h1 \ h3 have y @ z \in L_1 ;; L_2
        by (drule-tac\ A=L_1\ in\ seq-intro,\ auto\ elim:prefixE)
     ultimately show ?thesis by blast
   qed
  — ?thesis is proved by exploiting the symmetry of eq-tag:
 from this [OF - eq-tag] and this [OF - eq-tag [THEN sym]]
   show ?thesis unfolding str-eq-def str-eq-rel-def by blast
lemma quot-seq-finiteI [intro]:
```

```
fixes L1 L2::lang assumes fin1: finite (UNIV // \approxL1) and fin2: finite (UNIV // \approxL2) shows finite (UNIV // \approxL1; L2)) proof (rule-tac tag = tag-str-SEQ L1 L2 in tag-finite-imageD) show \wedgex y. tag-str-SEQ L1 L2 x = tag-str-SEQ L1 L2 y \Longrightarrow x \approx(L1 ;; L2) y by (rule tag-str-SEQ-injI) next have *: finite ((UNIV // \approxL1) \times (Pow (UNIV // \approxL2))) using fin1 fin2 by auto show finite (range (tag-str-SEQ L1 L2)) unfolding tag-str-SEQ-def apply(rule finite-subset[OF - *]) unfolding quotient-def by auto qed
```

1.2.6 The inductive case for STAR

This turned out to be the trickiest case. The essential goal is to proved $y @ z \in L_1*$ under the assumptions that $x @ z \in L_1*$ and that x and y have the same tag. The reasoning goes as the following:

- 1. Since $x @ z \in L_1*$ holds, a prefix xa of x can be found such that $xa \in L_1*$ and $(x xa)@z \in L_1*$, as shown in Fig. 2(a). Such a prefix always exists, xa = [], for example, is one.
- 2. There could be many but fintie many of such xa, from which we can find the longest and name it xa-max, as shown in Fig. 2(b).
- 3. The next step is to split z into za and zb such that (x xa max) @ $za \in L_1$ and $zb \in L_1*$ as shown in Fig. 2(e). Such a split always exists because:
 - (a) Because $(x x\text{-}max) @ z \in L_1*$, it can always be splitted into prefix a and suffix b, such that $a \in L_1$ and $b \in L_1*$, as shown in Fig. 2(c).
 - (b) But the prefix a CANNOT be shorter than x xa-max (as shown in Fig. 2(d)), becasue otherwise, ma-max@a would be in the same kind as xa-max but with a larger size, conflicting with the fact that xa-max is the longest.
- 4. By the assumption that x and y have the same tag, the structure on x @ z can be transferred to y @ z as shown in Fig. 2(f). The detailed steps are:
 - (a) A y-prefix ya corresponding to xa can be found, which satisfies conditions: $ya \in L_1*$ and $(y ya)@za \in L_1$.

- (b) Since we already know $zb \in L_1*$, we get $(y ya)@za@zb \in L_1*$, and this is just $(y ya)@z \in L_1*$.
- (c) With fact $ya \in L_1*$, we finally get $y@z \in L_1*$.

The formal proof of lemma tag-str-STAR-injI faithfully follows this informal argument while the tagging function tag-str-STAR is defined to make the transfer in step ?? feasible.

```

```

lemma tag-str-STAR-injI:

fixes v w

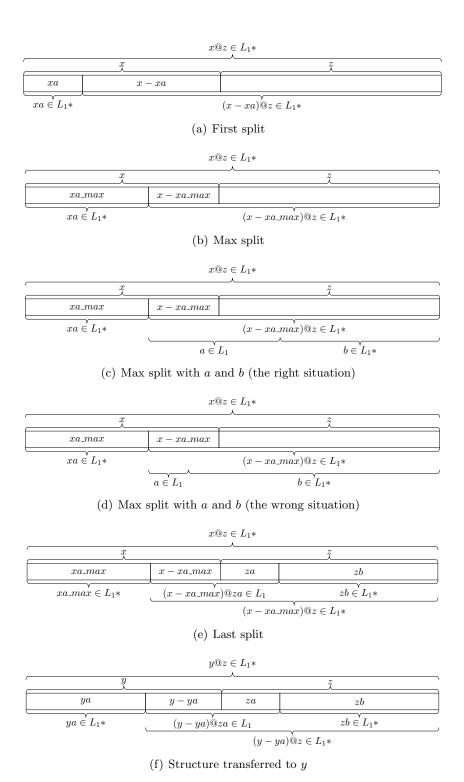

Figure 2: The case for STAR

```
assumes eq-tag: tag-str-STAR L_1 v = tag-str-STAR L_1 w
 shows (v::string) \approx (L_1 \star) w
proof-
    - As explained before, a pattern for just one direction needs to be dealt with:
  \{ \mathbf{fix} \ x \ y \ z \}
   assume xz-in-star: x @ z \in L_1 \star
     and tag-xy: tag-str-STAR L_1 x = tag-str-STAR L_1 y
   have y @ z \in L_1 \star
   \mathbf{proof}(cases\ x = [])
       - The degenerated case when x is a null string is easy to prove:
     case True
     with tag-xy have y = []
       by (auto simp add: tag-str-STAR-def strict-prefix-def)
     thus ?thesis using xz-in-star True by simp
   next
         - The nontrival case:
     case False
         Since x @ z \in L_1 \star, x can always be splitted by a prefix xa together
         with its suffix x - xa, such that both xa and (x - xa) @ z are
         in L_1\star, and there could be many such splittings. Therefore, the
         following set ?S is nonempty, and finite as well:
     let ?S = \{xa. \ xa < x \land xa \in L_1 \star \land (x - xa) \ @ \ z \in L_1 \star \}
     have finite ?S
       by (rule-tac B = \{xa. \ xa < x\} in finite-subset,
         auto simp:finite-strict-prefix-set)
     moreover have ?S \neq \{\} using False xz-in-star
       by (simp, rule-tac \ x = [] \ in \ exI, \ auto \ simp:strict-prefix-def)
         Since ?S is finite, we can always single out the longest and
     name it xa-max: ultimately have \exists xa-max \in ?S. \forall xa \in ?S. length xa \leq length xa-max
       using finite-set-has-max by blast
     then obtain xa-max
       where h1: xa\text{-}max < x
       and h2: xa\text{-}max \in L_1 \star
       and h3: (x - xa\text{-}max) @ z \in L_1 \star
       and h_4: \forall xa < x. xa \in L_1 \star \land (x - xa) @ z \in L_1 \star
                                   \longrightarrow length \ xa < length \ xa-max
       by blast
        By the equality of tags, the counterpart of xa-max among y-
         prefixes, named ya, can be found:
     obtain ya
       where h5: ya < y and h6: ya \in L_1 \star
       and eq-xya: (x - xa\text{-}max) \approx L_1 (y - ya)
     proof-
       from tag-xy have \{\approx L_1 \text{ "} \{x - xa\} \mid xa. xa < x \land xa \in L_1\star\} =
         \{\approx L_1 \text{ "} \{y-xa\} \mid xa. xa < y \land xa \in L_1\star\} \text{ (is ?left = ?right)}
         by (auto\ simp:tag-str-STAR-def)
       moreover have \approx L_1 " \{x - xa\text{-}max\} \in ?left \text{ using } h1 \ h2 \text{ by } auto
       ultimately have \approx L_1 "\{x - xa\text{-}max\} \in \text{?right by } simp
       with prems show ?thesis apply
         (simp add:Image-def str-eq-rel-def str-eq-def) by blast
```

```
qed
   The ?thesis, y @ z \in L_1 \star, is a simple consequence of the following
  proposition:
have (y - ya) @ z \in L_1 \star
proof-
   The idea is to split the suffix z into za and zb, such that:
 obtain za zb where eq-zab: z = za @ zb
   and l-za: (y - ya)@za \in L_1 and ls-zb: zb \in L_1 \star
 proof -
     - Since xa-max < x, x can be splitted into a and b such that:
   from h1 have (x - xa - max) @ z \neq []
     by (auto simp:strict-prefix-def elim:prefixE)
   from star-decom [OF h3 this]
   obtain a b where a-in: a \in L_1
     and a-neq: a \neq [] and b-in: b \in L_1 \star
    and ab-max: (x - xa\text{-max}) @ z = a @ b by blast
   — Now the candiates for za and zb are found:
   let ?za = a - (x - xa - max) and ?zb = b
   have pfx: (x - xa - max) \le a (is ?P1)
     and eq-z: z = ?za @ ?zb (is ?P2)
   proof -
        Since (x - xa\text{-}max) @ z = a @ b, string (x - xa\text{-}max) @ z can
       be splitted in two ways:
    have ((x - xa\text{-}max) \le a \land (a - (x - xa\text{-}max)) @ b = z) \lor
      (a < (x - xa - max) \land ((x - xa - max) - a) @ z = b)
      using app-eq-dest[OF ab-max] by (auto simp:strict-prefix-def)
     moreover {
        - However, the undsired way can be refuted by absurdity:
      assume np: a < (x - xa - max)
        and b-eqs: ((x - xa - max) - a) @ z = b
      have False
      proof -
        let ?xa\text{-}max' = xa\text{-}max @ a
        have ?xa\text{-}max' < x
          using np h1 by (clarsimp simp:strict-prefix-def diff-prefix)
        moreover have ?xa\text{-}max' \in L_1 \star
          using a-in h2 by (simp add:star-intro3)
        moreover have (x - ?xa - max') @ z \in L_1 \star
          using b-eqs b-in np h1 by (simp add:diff-diff-appd)
        moreover have \neg (length ?xa-max' \leq length xa-max)
         using a-neg by simp
        ultimately show ?thesis using h4 by blast
      qed }
        Now it can be shown that the splitting goes the way we desired.
     ultimately show ?P1 and ?P2 by auto
   hence (x - xa\text{-}max)@?za \in L_1 using a-in by (auto elim:prefixE)
   — Now candidates ?za and ?zb have all the required properties.
   with eq-xya have (y - ya) @ ?za \in L_1
    by (auto simp:str-eq-def str-eq-rel-def)
```

```
with eq-z and b-in prems
         show ?thesis by blast
       qed
          ?thesis can easily be shown using properties of za and zb:
       have ((y - ya) @ za) @ zb \in L_1 \star  using l-za ls-zb by blast
       with eq-zab show ?thesis by simp
     qed
     with h5 h6 show ?thesis

qed
lemma — The oringal version with less explicit details.
 assumes eq-tag: tag-str-STAR L_1 v = tag-str-STAR L_1 w
 shows (v::string) \approx (L_1 \star) w
proof-
       According to the definition of \approx Lang, proving v \approx (L_1 \star) w amounts
       to showing: for any string u, if v @ u \in (L_1 \star) then w @ u \in (L_1 \star)
      and vice versa. The reasoning pattern for both directions are the
       same, as derived in the following:
  \{ \mathbf{fix} \ x \ y \ z \}
   assume xz-in-star: x @ z \in L_1 \star
     and tag-xy: tag-str-STAR L_1 x = tag-str-STAR L_1 y
   have y @ z \in L_1 \star
   proof(cases x = [])
       - The degenerated case when x is a null string is easy to prove:
     case True
     with tag-xy have y = []
       by (auto simp:tag-str-STAR-def strict-prefix-def)
     thus ?thesis using xz-in-star True by simp
         - The case when x is not null, and x @ z is in L_1 \star,
     case False
     obtain x-max
       where h1: x\text{-}max < x
       and h2: x\text{-}max \in L_1 \star
       and h3: (x - x\text{-}max) @ z \in L_1 \star
       and h_4: \forall xa < x. xa \in L_1 \star \land (x - xa) @ z \in L_1 \star
                                 \longrightarrow length \ xa \leq length \ x\text{-max}
     proof-
       let ?S = \{xa. \ xa < x \land xa \in L_1 \star \land (x - xa) @ z \in L_1 \star \}
