Homework 5

- 1. What can attacker that controls the network do to a communication between a client and a server?
- 2. Before starting a TCP connection, client and servers perform a three-way handshake. Describe how can this three-way handshake can be abused by an attacker?
- 3. Consider the following simple mutual authentication protocol:

$$A \rightarrow B$$
: N_a
 $B \rightarrow A$: $\{N_a, N_b\}_{K_{ab}}$
 $A \rightarrow B$: N_b

Explain how an attacker B' can launch an impersonation attack by intercepting all messages for B and make A decrypt her own challenges.

4. What is the main problem with the following authentication protocol where *A* sends *B* mutually shared key?

$$A \rightarrow B : K_{AB}$$

5. Nonces are unpredicatble random numbers used in protocols? Consider the following protocol

$$A \rightarrow B$$
: N
 $B \rightarrow A$: $\{N+1\}_{K_{ab}}$

Write down three facts that *A* can infer after this protocol has been successfully completed?

6. (**Deleted**: same as 2) Before starting a TCP connection, client and servers perform a three-way handshake:

$$A \rightarrow S$$
: SYN
 $S \rightarrow A$: SYN-ACK
 $A \rightarrow S$: ACK

How can this protocol be abused causing trouble on the server?

- 7. Write down a protocol which establishes a secret key between *A* and *B* using a mutually trusted third party *S*. You can assume *A* and *S*, respectfully *B* and *S*, share secret keys.
- 8. Consider the following protocol between a car and a key transponder:

- (a) C generates a random number N
- (b) C calculates $(F,G) = \{N\}_K$
- (c) $C \rightarrow T: N, F$
- (d) T calculates $(F', G') = \{N\}_K$
- (e) T checks that F = F'
- (f) $T \rightarrow C: N, G'$
- (g) C checks that G = G'

In Step 2 and 4 a message is split into two halves. Explain what the purpose of this split is? Assume the key *K* is shared only between the car and the transponder. Does the protocol achieve that the transponder *T* authenticates itself to the car *C*? Does the car authenticate itself to the transponder?
